ABSTRACT

Ovarian tumor cells produce macrophage colony stimulating factor, a potent chemoattractant for monocytes. Monocytes and macrophages produce tumor necrosis factor α (TNF-α) and interleukin-1α or interleukin 1β (IL-1β) that can stimulate ovarian tumor cell growth. The present study has explored whether paracrine stimulation by monocyte-derived cytokines might induce autocrine growth stimulation of normal and malignant ovarian epithelial cells. Endogenous expression of TNF-α mRNA was detected in ascites ovarian cancer cells isolated directly from patients, but not in established cultures of normal or malignant ovarian epithelial cells. When ascites tumor cells were cultured for 7 days, TNF-α expression ceased but could be reinduced by treatment with TNF-α or IL-1β. Ascites fluid contained concentrations of the cytokines that could mediate these effects. Similarly, treatment of normal or malignant ovarian epithelial cells with purificed recombinant IL-1β or TNF-α induced transcription of TNF-α mRNA within 1 h. TNF-α protein could be detected by enzyme-linked immunosorbant assay in conditioned medium from IL-1β treated ovarian cancer cells. [3H]Thymidine incorporation by normal or malignant ovarian epithelial cells stimulated with purificed recombinant IL-1β or TNF-α. Stimulation of proliferation by IL-1β could be partially blocked by an antibody against TNF-α or by soluble TNF-α receptor. Thus, TNF-α may function as both an autocrine and a paracrine growth factor in ovarian cancer.

INTRODUCTION

TNF-α and IL-1 are cytokines produced primarily by monocytes and macrophages. TNF-α and IL-1 share several biological activities, despite the fact that they are structurally unrelated and bind to different cell surface receptors (1, 2). Both TNF-α and IL-1 can inhibit the growth of certain tumor cells (3-5), stimulate human fibroblast proliferation, promote bone resorption by osteoclasts, down-regulate lipogenic gene expression, and stimulate the production of collagenase in synovial cells (6). Conversely, TNF-α and IL-1 can also stimulate the growth of normal cells as well as certain cancer cells in culture (6, 7). Since TNF-α can be constitutively produced by malignant cells (8), its expression could contribute to tumor progression and spread (9, 10) as well as indicate resistance to the cytotoxicity of exogenous TNF-α (11).

Ovarian cancer is the leading cause of death from gynecological malignancy. Over 60% of patients present with disease that has spread beyond the pelvis and into the peritoneal cavity (12). Although metastatic disease can be treated with cytoreductive surgery and combination chemotherapy, the survival of these patients is poor. Recent studies have focused on factors that regulate the growth of malignant ovarian epithelium (13), with the expectation that a more fundamental understanding of these factors might suggest novel and potentially more effective approaches to treatment.

Macrophages are found in solid tumor implants of ovarian cancer as well as in ascites fluid (14, 15). Previous studies have indicated that ovarian cancer cells produce macrophage colony stimulating factor which is a potent chemoattractant for monocytes (16-18). Monocyte derived cytokines including TNF-α, IL-1, and interleukin 6 can stimulate proliferation of ovarian cancer cells (7). Other investigators have shown that ovarian and other cancer cells express TNF-α in vitro and in vivo (8, 19, 20). Whether or not endogenous expression of TNF-α is important for growth of ovarian cancer cells remains to be resolved.

In this article, we have explored the possibility that endogenous expression of TNF-α is maintained in vivo by exogenous TNF-α or IL-1 and that endogenous production of TNF-α may trigger tumor cell proliferation.

MATERIALS AND METHODS

Cytokines, Anti-Cytokine Antibodies, and DNA Probes. Human recombinant TNF-α (2 x 10^7 units/mg) was purchased from Genzyme (Boston, MA). Human recombinant IL-1β (5 x 10^7 units/mg) and human recombinant IL-1α (5 x 10^7 units/mg) were purchased from R&D Systems (Minneapolis, MN). Murine anti-human TNF-α monoclonal antibody was purchased from Endogen, Inc. (Boston, MA). Soluble TNF-α receptor (TNF-BP I) was purchased from R&D Systems. A cDNA probe for human TNF-α in plasmid pCDV1 was purchased from the American Type Culture Collection (Bethesda, MD).

Cell Cultures. Four ovarian cancer cell lines, OVCA 420, OVCA 429, OVCA 432, and OVCA 433, were established from ascites tumor cells of ovarian cancer patients (21). The cells were grown in Eagle’s minimal essential medium that was supplemented with 10% FBS, 2 mM L-glutamine, 100 units/ml penicillin, 100 μg/ml streptomycin, 1 mM sodium pyruvate, and 1% nonessential amino acid mixture. The ovarian cancer cell line SKOv3 was obtained from the American Type Culture Collection. SKOv3 cells were cultured in McCoy’s medium containing 15% FBS, 2 mM L-glutamine, 100 units/ml penicillin, and 100 μg/ml streptomycin. The OVCAR-3 cell line was obtained from Dr. Thomas C. Hamilton and was cultured in RPMI 1640 containing 15% FBS, 2 mM L-glutamine, 100 units/ml penicillin, and 100 μg/ml streptomycin. Four cultures of normal surface ovarian epithelial cells N-OSE 006R, N-OSE 007L, N-OSE 038L, and N-OSE 039R were established in our laboratory as described previously (22). The epithelial origin of the cultured cells was confirmed by immunocytochemical detection of cytokeratin and the identification of characteristic structures was confirmed by electron microscopy. Cells were grown in medium containing equal volumes of MCDB 105 and medium 199 supplemented with 15% FBS, 2 mM L-glutamine, 100 units/ml penicillin, and 100 μg/ml streptomycin. Medium was changed every 3 days and the cells were subcultured once a week. For subculture and experiments, monolayers were detached with 0.25% trypsin-0.02% EDTA.

Separation of Tumor Cells from Ascites. Ascites fluid was obtained from ovarian cancer patients at the time of surgery. The cells were pelleted by centrifugation, frozen in 10% dimethyl sulfoxide, and stored in the vapor phase of liquid nitrogen. For each experiment, cells were thawed, resuspended in HBSS, and separated on Percoll (Pharmacia, Piscataway, NJ) density gradients. After centrifugation at 1500 rpm for 20 min at room temperature, fractions were collected and washed 3 times with HBSS. Cells were incubated with mouse monoclonal antibodies reactive with ovarian tumor associated antigens including 317G5, 260F9, BT8FF1, and BT4Z4 for 1 h at 4°C. Cells were washed 3 times with HBSS and incubated with goat anti-mouse immunoglo-
bulin coated beads (Dynabeads; Dynal A.S., Oslo, Norway) for 1 h. Rossetted cells were collected with a magnet. More than 99% of the cells bound OC125 and AE1 detected by immunocytochemistry with avidin-biotin-complex immunoperoxidase, whereas <1% of cells reacted with antibodies against IL-1α. Total cellular RNA was isolated as described. For cell culture and treatment, 106 purified tumor cells were cultured in 100-mm dishes in medium 199/105 as described above at 37°C in 5% CO2 and 95% humidified air. On day 7, cells were treated with TNF-α or IL-1 (1 ng/ml) for 1 or 2 h, and total cellular RNA was isolated.

RNA Isolation and Northern Transfers. Total cellular RNA was isolated using guanidinium isothiocyanate/cesium chloride (23) from 4 normal ovarian epithelial cell cultures, 5 ovarian cancer cell lines, and 5 samples of ascites tumor cells from different patients. Purified RNA (10–20 µg) was analyzed by electrophoresis in 1% agarose/6% formaldehyde gel followed by blot transfer to Genescreen Plus membranes (Dupont, Boston, MA). Human TNF-α and β-actin cDNA probes were labeled with [32P]dCTP using a multiprime DNA labeling kit (Amersham, Arlington Heights, IL). Labeled probes were purified on Sepharose-G50 columns (Pharmacia). Transfer membranes were prehybridized in 50% formamide, 10% dextran sulfate, 1% SDS, and 1 µg/ml denatured salmon sperm DNA at 42°C for 1 h. Membranes were then hybridized at 42°C for approximately 16 h in the same buffer containing 106 cpm/ml heat-denatured TNF-α cDNA probe. Membranes were washed once for 30 min at room temperature in 2 × SSC with 0.1% SDS, once for 30 min in 0.5 × SSC with 0.1% SDS, and once for 30 min at 65°C in 0.1 × SSC with 0.1% SDS prior to autoradiography. Autoradiograms were exposed at −70°C over 2–10 days in the presence of an intensifying screen. After autoradiography the membranes were stripped and rehybridized with a β-actin cDNA probe.

Nuclear Run-on Assay. OVCA 432 cells were grown in tissue culture flasks to near confluence and the cells (5 × 105) were treated with 1 ng/ml of TNF-α or IL-1β for 10 min or 1 h. Cells were washed 3 times with ice-cold phosphate buffered saline, scraped with a rubber policeman, and centrifuged at 500 g for 5 min. The cell pellet was resuspended in lysis buffer containing 0.25% SDS, and once for 30 min at 65°C in 0.1 X SSC with 0.1% SDS prior to autoradiography. All assays were performed with at least four replicates. In previous studies increases in [3H]thymidine incorporation by OVCA 432 cells correlated with increases in cell number (7). Statistical Analysis. Student’s t test was used to compare [3H]thymidine incorporation in control and experimental groups. Data were expressed as mean cpm ± SD.

RESULTS

TNF-α Gene Expression in Ascites Tumor Cells, Ovarian Cancer Cell Lines, and Normal Ovarian Epithelial Cells. A [32P]-labeled human TNF-α cDNA probe was hybridized with total cellular RNAs from 4 normal ovarian epithelial cell cultures, 5 ovarian cancer cell lines, and 4 preparations of ovarian cancer cells purified directly from ascites. TNF-α expression was seen in all four highly purified ascites tumor cell preparations, but not in any of the normal or malignant ovarian epithelial cell lines (Fig. 1).
 Cultures of OVCA 189 treated with 1 ng/ml of IL-1ß for 1 (Lane 3) or 2 h (Lane 4), and OVCA 189 cells (Lane 1), from 7 day cultures of OVCA 189 (Lane 2), from 7 day cultures of OVCA 189 treated with 1 ng/ml of IL-1ß for 1 (Lane 3) or 2 h (Lane 4), and 7 day cultures of OVCA 189 treated with TNF-α for 1 (Lane 5) or 2 h (Lane 6) were isolated directly from ascites fluid. Total cellular RNA (20 μg/lane) from freshly isolated T-actin.

*Mean ± SD determined by ELISA.

The induction of TNF-α mRNA depended on the concentration of cytokines and the duration of treatment. TNF-α mRNA levels reached a maximum after 1–2 h of treatment with IL-1β or TNF-α and subsequently declined (Fig. 3). Similar kinetics were observed after treatment with IL-1α (data not shown). As little as 0.01 ng/ml IL-1β induced TNF-α expression, whereas 0.1 ng/ml TNF-α was required to induce detectable endogenous expression of TNF-α (Fig. 4). Similar induction of TNF-α could be achieved with normal ovarian cell cultures and with several other ovarian cancer cell lines including OVCA 420, OVCA 429, OVCA 433, OVCA R3, and SK-Ov3. To determine whether expression of TNF-α transcripts was associated with production of TNF-α protein, culture supernatants were assayed for TNF-α by ELISA. TNF-α could not be detected in control supernatants, but TNF-α protein was detected after treatment with IL-1β. In the presence of IL-1β, TNF-α levels increased from 50–2000 pg/ml over 8 h (Table 2). In the presence of 1 ng/ml of exogenously added TNF-α, it was not possible to measure a time dependent increase in TNF-α levels (Table 2). Induction of TNF-α was also observed with freshly isolated ovarian cancer ascites cells. After 24 h in culture 3 × 10^5 OVCA 189 cells produced up to 135 pg/ml TNF-α in the culture supernatant. After 6 days in culture <48 pg/ml TNF-α could be detected. TNF production could, however, be reinduced (52.4–63.6 pg/ml) by incubation with 1 ng/ml IL-1β.

Transcription of TNF-α mRNA in Ovarian Cancer Cells. To determine whether increased levels of TNF-α mRNA resulted from increased transcription, nuclear run-on analysis was performed with OVCA 432 cells following stimulation with TNF-α or IL-1β (Fig. 5). Transcription of TNF-α message was increased by both TNF-α and IL-1β.

Stimulation of [3H]Thymidine Incorporation by TNF-α and IL-1β. In an earlier study we had shown that treatment for 24 h with TNF-α or IL-1 could stimulate a dose dependent increase in [3H]thymidine incorporation and cell number by ovarian cancer cell lines. Around a 30–200% increase in proliferation by these parameters was observed in sensitive cell lines including OVCA 429 (7), OVCA 432 (7), OVCA 433 (7), OVCA R3, and SK-Ov3 (Table 3). In the present study we have determined whether TNF-α or IL-1β could stimulate proliferation of normal ovarian epithelial cells. After treatment for 24 h with IL-1β, or TNF-α, increased [3H]thymidine incorporation was observed in normal ovarian epithelial cells (Fig. 6).
TNF-α as a growth factor for ovarian cancer

Blocking of TNF-α or IL-1β induced [3H]thymidine incorporation with anti-TNF-α antibody or soluble TNF-α receptor.

Since IL-1β could stimulate proliferation of ovarian cancer cells as well as induce TNF-α expression, we have evaluated the possibility that TNF-α could act as an autocrine growth factor. To test whether endogenous expression of TNF-α might be a critical factor triggering tumor cell proliferation, blocking studies were performed in two separate experiments with anti-TNF-α antibody (Fig. 7A) and TNF-α receptor (Fig. 7B). TNF-α mediated stimulation of [3H]thymidine incorporation by ovarian cancer cell line OVCA 432 could be blocked with anti-TNF-α antibody (Fig. 7A) or TNF-α receptor (Fig. 7B). TNF-α induced stimulation was inhibited by 80% with anti-TNF-α antibody (1:50) and by 60% with soluble TNF-α receptor. In this experiment, blocking of proliferation could relate to neutralization either of TNF-α added to the cultures or of TNF-α produced endogenously and released into the culture medium. More definitive data could be obtained by blocking IL-1β induced stimulation of [3H]thymidine incorporation. Consistent with the possibility that endogenous production of TNF-α was linked to cell proliferation, IL-1β induced stimulation was inhibited by 53% with anti-TNF-α antibody (1:50) and by 92% with soluble TNF-α receptor (Fig. 7, A and B).

DISCUSSION

Our studies support the possibility that TNF-α acts as both a paracrine and an autocrine growth factor for normal and malignant ovarian epithelium. Ovarian cancer cells produce macrophage colony stimulating factor, a potent chemotactrant for mononuclear phagocytes. Macrophages are associated with ovarian cancer cells both in ascites fluid (15) and in solid tumors (14, 15). Cytokines produced by macrophages, including IL-1α, interleukin 6, and TNF-α can stimulate proliferation of ovarian cancer cells (7). Significant levels of TNF-α have been found in the plasma of certain cancer patients (24). Ascites fluid from the patients in our study all contained detectable TNF protein ranging from 116 to 1450 pg/ml. Although IL-1β could not be detected, IL-1α levels ranged from 2 to 14 pg/ml. Since we tested only 5 ovarian cancer patient ascites fluids for IL-1, it is possible that other patients may have detectable levels of IL-1. Continued exposure to these cytokines may be important not only for proliferation, but also for endogenous expression of TNF-α.

Our study confirms earlier observations that ovarian cancer cells can express TNF-α both in vitro and in vivo (8, 19). In one study, TNF-α was found in tumor cells from 4 of 5 ascites and in 16 of 20 tissue sections (19). TNF-α or TNF-α-like molecules were also produced by some tumor cell lines in vitro (8), but the expression of TNF-α was not constitutive and the endogenous production of TNF could be induced by exogenous TNF-α. In our present report, each of 5 tumor cell preparations from ascites expressed TNF-α, but TNF-α expression was lost during 7 days of incubation in culture. Endogenous expression of TNF-α could be reinduced by treatment with TNF-α or with IL-1β. Although many of the experiments in our present report have been performed with IL-1β, IL-1α has stimulated proliferation of ovarian tumor cell lines (7) and can induce TNF-α with kinetics similar to those produced by IL-1β. Expression of TNF-α by ovarian cancer cell lines was induced by TNF-α or IL-1 in a time and dose dependent manner. Higher levels of TNF-α mRNA resulted from increased transcription judged by nuclear run-on assays.
epithelial cells. Normal ovarian cells were plated at 5 X KrVwell. ['H]Thymidine incorporation was measured after incubation with TNF-a or IL-1ß for 24 h. Data reflect the cultures of OVCA 432 cells. ['H]Thymidine incorporation was measured after 24 h. TNF-a (1 ng/ml) was preincubated with medium, different concentrations of monoclonal stimulated cells.

Results are expressed as mean cpm ± SD. *, significant stimulation (P < 0.05) relative anti-TNF-a antibody (A) or soluble TNF receptor (fl) for 2 h at 37°C before addition to Table 3 Effect of IL-1 and TNF-a on ['H]thymidine incorporation by ovarian cancer cell lines

Fig. 6. Effect of TNF-a and IL-1ß on ['H]thymidine incorporation by normal ovarian epithelial cells. Normal ovarian cells were plated at 5 X 10⁴/well. ['H]Thymidine incorporation was measured after incubation with TNF-a or IL-1ß for 24 h. Data reflect the mean cpm ± SD. *, statistically significant stimulation (P < 0.05).

Fig. 7. Effect of anti-TNF-a antibody or soluble TNF-a receptor on the stimulation of proliferation induced by IL-1ß or TNF-a in ovarian cancer cells. IL-1ß (1 ng/ml) or TNF-a (1 ng/ml) was preincubated with medium, different concentrations of monoclonal anti-TNF-a antibody (A) or soluble TNF receptor (B) for 2 h at 37°C, before addition to cultures of OVCA 432 cells. ['H]Thymidine incorporation was measured after 24 h. Results are expressed as mean cpm ± SD. *, significant stimulation (P < 0.05) relative to the medium control. †, significant reduction (P < 0.05) relative to the IL-1ß or TNF-a stimulated cells.

The expression of TNF-α mRNA was also accompanied by translation of TNF-α protein since the supernatants of IL-1 treated cultures contained TNF-α that could be detected by ELISA.

Endogenous expression of TNF-α may contribute to the proliferative activity of exogenous TNF-α or IL-1ß. When IL-1ß was used to stimulate proliferation and to induce TNF-α, the growth stimulating activity of IL-1ß was partially blocked by monoclonal anti-TNF-α antibodies or soluble TNF receptor. Failure to block IL-1ß-induced proliferation completely may relate to several factors. (a) The concentration of anti-TNF-α-antibody might be insufficient to neutralize the high levels of TNF induced by IL-1. The concentrations of antibodies and receptors used could neutralize approximately 1 ng/ml of TNF-α. (b) Intracellular TNF-α might provide a mitogenic signal. The anti-TNF-α antibodies and receptors can probably neutralize only extracellular TNF-α. TNF has exerted a mitogenic effect after micro-injection into macrophages (25). (c) IL-1 could also act through pathway(s) that do not utilize TNF-α to mediate cell growth (26). Taken together, however, our data suggest that TNF-α might act through autocrine as well as paracrine pathways to stimulate rather than to inhibit ovarian cancer growth.

The ability to respond to TNF-α or IL-1 might be acquired by ovarian tumor cells during malignant transformation or might simply reflect the physiological response of the normal ovarian surface epithelial cells from which these tumors are derived. In our present study, TNF-α and IL-1ß significantly stimulated proliferation of normal ovarian epithelial cells in culture. Both IL-1α and IL-1ß are expressed by human ovarian granulosa cells obtained from preovulatory follicular aspirates (27). IL-1 has also been detected in follicular fluid and might provide a critical signal to stimulate the focal proliferation of ovarian epithelium at the time of ovulation, facilitating repair of the defect produced when the follicle ruptures.

Several clinical trials have been conducted using TNF-α to treat ovarian cancer (28, 29). The clinical efficacy of TNF-α appears to be poor with an overall response rate of <5% (28). A poor response rate may relate to the innate resistance of ovarian tumor cells to TNF-α mediated cytotoxicity. Endogenous expression of TNF-α has correlated with resistance to the cytotoxic effects of TNF-α in some tumor cells (11). Given the technical difficulties in monitoring ovarian tumor growth within clinical trials, it is also possible that treatment with the cytokine might have actually accelerated tumor growth in some patients. Conversely, strategies to inhibit TNF-α expression and activity might provide a novel approach to treatment of at least some ovarian cancer patients.
