Monoclonal Antibodies to the Extracellular Domain of Prostate-specific Membrane Antigen Also React with Tumor Vascular Endothelium

Abstract

Prostate-specific membrane antigen (PSMA), initially defined by monoclonal antibody (mAb) 7E11, is a now well-characterized type 2 integral membrane glycoprotein expressed in a highly restricted manner by prostate epithelial cells. 7E11 has been shown to bind an intracellular epitope of PSMA that, in viable cells, is not available for binding. Herein, we report the initial characterization of the first four reported IgG mAbs that bind the external domain of PSMA. Competitive binding studies indicate these antibodies define two distinct, noncompeting epitopes on the extracellular domain of PSMA. In contrast to 7E11, these mAbs bind to viable LNCaP cells in vitro. In addition, they maintain strong immunohistochemical reactivity to tissue sections of prostate epithelia, including prostate cancer. These mAbs were also strongly reactive with vascular endothelium within a wide variety of carcinomas (including lung, colon, breast, and others) but not with normal vascular endothelium. These antibodies should prove useful for in vivo targeting to prostate cancer, as well as to the vascular compartment of a wide variety of carcinomas.

Introduction

PSMA is a highly restricted prostate epithelial cell membrane glycoprotein of approximately 100 kDa (1, 2). The PSMA gene has been cloned, sequenced (2), and mapped to chromosome 11q14 (3). In contrast to other highly restricted prostate-related antigens such as PSA, prostate acid phosphatase, and PSP, which are secretory proteins, PSMA is an integral membrane protein. Among the reasons for significant interest in PSMA is that it is ideal for in vivo prostate-specific targeting strategies. In addition to its prostate specificity (1, 2, 4, 5), PSMA is expressed by a very high proportion of PCa (6); this expression is further increased in higher-grade cancers, in metastatic disease (6), and in hormone-refractory PCa (5—7).

The initial validation of PSMA as an in vivo target has been borne out by imaging trials with mAb 7E11/CYT-356 (8—11). However, epitope mapping indicates that 7E11/CYT-356 targets an intracellular epitope (12, 13). Successful imaging with 7E11/CYT-356 probably relates to the targeting of dead/dying cells within tumor sites (6, 12, 13). It has been noted (2, 12—14) that a mAb to the extracellular domain would provide benefits, including improved in vivo localization and enhanced imaging and therapy. In this study, we report the development of four IgG mAbs to the external domain of PSMA. These mAbs also have been found reactive to vascular endothelium within a wide range of carcinomas but not with normal endothelial cells.

Materials and Methods

Generation and Production of mAb. BALB/c mice were immunized three times with LNCaP cells or a primary culture of PCa epithelial cells. Spleen cells were fused with X63.Ag.653 mouse myeloma cells using standard hybridoma technique. Clones that were reactive against LNCaP but unreactive against tissue sections of normal kidney (with the exception of some proximal tubule reactivity) and colon were subcloned. Murine ascites fluid was produced, and mAbs were purified using protein G (Pharmacia LKB Biotechnol, Piscataway, NJ). Purified mAb 7E11 was a generous gift from Dr. Gerald P. Murphy (Pacific Northwest Research Foundation, Seattle, WA).

Immunohistochemical Staining. Normal and cancer tissues were precooled in liquid nitrogen, snap-frozen in OCT compound (Miles Inc., Elkhart, IN) on dry ice, and stored at −80°C. Cryostat tissue sections (5 μm) were incubated in cold acetone (4°C) for 10 min. mAbs (5 μg/ml or hybridoma supernatants) were incubated for 1 h at RT. Antibody binding was detected using rabbit antimouse immunoglobulin-peroxidase (DAKO Corp., Carpinteria, CA) as a secondary antibody and diaminobenzidine (Sigma Chemical Co., St. Louis, MO) as chromogen. Isotype-matched irrelevant antibody was used as a negative control.

Cross Immunoprecipitation. LNCaP cells were lysed in lysis buffer [20 mM Tris/HCl, pH 8; 1 mM EDTA; 1 mM phenylmethylsulfonyl fluoride; and 1% (v/v) Triton X-100]. The resulting lysate was precleared by incubation with protein G beads overnight at 4°C, then incubated with mAb for 2 h. Protein G beads were added for 90 min prior to further washing. The beads were resuspended and boiled for 5 min in 1× Laemmli sample buffer containing 2-mercaptoethanol at 5% final concentration. The samples were centrifuged, and supernatant was recovered and placed on a 12% SDS-PAGE gel. After electrophoresis, the separated proteins were transferred to a nitrocellulose membrane. The membranes were blocked with 5% dry milk/TBST (Triton-buffered saline-Tween 20), incubated with primary mAbs × 60 min and followed by sheep antimouse immunoglobulin-peroxidase (Amersham Corp., Cleveland, OH). After washing, the membranes were developed using the enhanced chemiluminescence method (Amersham). Either 0.15 μg/ml J591 or 0.5 μg/ml 7E11 was used as a probe to detect the protein that was immunoprecipitated by 7E11, J591, J533, J415, and E99, respectively. Isotype-matched irrelevant antibody (I56; reactive to PSP) was used as a negative control.

IF Assay. LNCaP cells were grown on glass coverslips. IF assays were performed using either viable or fixed cells, the latter being either permeabilized or nonpermeabilized. For fixation, cells were treated with 2% paraformaldehyde-PBS (PBS, pH 7.4) for 30 min at RT, which does not permeabilize the cell membrane, washed with 1% BSA-PBS, quenched for 10 min in 50 mM NH₄Cl in PBS, and rinsed with 1% BSA-PBS. Where cell membrane perme-

Fig. 1. Cross immunoprecipitation shows mAbs J591, J415, J533, E99, and 7E11 recognize the same antigen. Lane 1, crude LNCaP lysate. In Lanes 2-7, LNCaP lysate was immunoprecipitated with 5 μg/ml mAb 7E11 (Lane 2); 5 μg/ml J591 (Lane 3); 10 μg/ml J533 (Lane 4); 10 μg/ml J415 (Lane 5); 10 μg/ml E99 (Lane 6); and 10 μg/ml 156 (to PSP; Lane 7). Immunoprecipitates were immunoblotted with 0.15 μg/ml mAb J591, (A) or 0.5 μg/ml 7E11 (B).

Fig. 2. Immunohistochemical reactivity of mAb J591 to neovasculature of renal (A), urothelial (B), colon (C), lung (squamous; D), breast carcinomas (E), and metastatic adenocarcinoma to liver (F). ×250.
Fig. 3. Immunofluorescence assay comparing the reactivity of mAbs J591, 1415, J533, and E99 to 7E11 on nonpermeabilized and permeabilized LNCaP cells. Intact, nonpermeabilized cells are reactive with mAbs J591 (A), J533 (C), J415 (E), and E99 (G) but not 7E11 (I). Reactivity is limited to the cell membrane without cytoplasmic staining, as mAbs do not enter the intact cells. Failure of 7E11 to bind (I) is consistent with the intracellular location of its epitope. When the cells are permeabilized prior to mAb incubation (B, D, F, H, J), reactivity to both cytoplasmic and membrane PSMA is seen. After the permeabilization and exposure of the intracellular PSMA epitope, 7E11 does bind. X1500.

Results

From over 2000 clones screened, 4 clones that reacted with a 100-kDa band on Western blots and that produced strong immunohistochemical staining of prostate epithelium were selected for further characterization.

Immunoprecipitation/Immunoblot. In Western blot analysis, mAbs J591 (IgG1), J533 (IgG1), J415 (IgG1), and E99 (IgG3), as well as 7E11, identified a 100-kDa band from LNCaP lysate but not from the PSMA-negative PC3 lysate (data not shown). To confirm that mAbs J591, J533, J415, and E99 detected the same antigen as 7E11, a cross-immunoprecipitation experiment was performed. Fig. 1 illustrates that the 100-kDa band that was immunoprecipitated by mAbs J591, J533, J415, E99, or 7E11 was detectable by immunoblot using either J591 or 7E11 as a probe (Fig. 1, A and B, respectively). Sequential immunoprecipitation studies (data not shown) also demonstrated that 7E11 and the four new mAbs can preclear reactivity to one another.

Immunohistochemical Reactivity. The reactivity of mAbs J591, J533, J415, and E99 with normal human tissues and cancers, with rare exception (vide infra), were similar to 7E11. Normal tissues with similar immunohistochemical reactivity included prostate (normal and hyperplastic glands demonstrated heterogeneous, weak to moderate staining intensity), kidney (subset of proximal...
IMMUNOELECTRON MICROSCOPY. IEM similarly demonstrated immunoreactivity of mAb J591 (Fig. 4A) but not 7E11 (Fig. 4B) with viable LNCaP cells. Furthermore, the IEM photomicrographs of mAb J591 show the gold particles localized to the extracellular face of the plasma membrane, confirming reactivity with the extracellular domain of PSMA.

COMPETITIVE BINDING ASSAY. A double antibody sandwich competition ELISA was used to determine whether the four mAbs recognize the same or different epitopes (Fig. 5). Each unlabeled mAb was able to block its biotinylated counterpart serving as a positive control. An unrelated IgG1 antibody (156) did not block any of the mAbs to PSMA. J591, J533, and E99 were each able to block each other, but were not blocked by J415. Conversely, J415 was blocked only by its unlabeled counterpart but not by any of the other three mAbs. These results indicate that J591, J533, and E99 recognize the same epitope that is distinct and noncross-reactive with the epitope recognized by J415.

Discussion

This study defines four new IgG mAbs that detect two distinct extracellular epitopes of PSMA (PSMAext1 and PSMAext2). The reactivity of these mAbs with PSMA has been defined by immunoprecipitation and immunoblotting studies and reactivity against cell lines (data not shown) and tissue sections using the 7E11 mAb as a reference. Immunoprecipitation and immunoblotting studies demonstrate identical reactivity to that seen with 7E11. Reactivity in vitro (data not shown) and on tissue sections of normal and neoplastic specimens demonstrates nearly identical results. The exceptions in immunohistochemical reactivity were limited to striated muscle and tumor vascular endothelium. Striated muscle is reactive with 7E11 but not with mAbs J591, J415, J533, or E99. 7E11 reactivity with striated muscle had been reported previously by Lopes et al. (4) who, like the present study, used frozen sections but has been reported as negative by Silver et al. (17) who studied paraffin sections. This discrepancy is most likely explained by some loss of 7E11/PSMA immunoreactivity in the fixation/embedding process. The difference in reactivity of 7E11 and the present mAbs to striated muscle, both herein studied on frozen sections, may represent differences in the posttranslational processing of PSMA (the external domain of which is heavily glycosylated) occurring in prostate as compared to muscle.

Reactivity of 7E11 with tumor but not normal vascular endothelium also was noted previously by Silver et al. (17), although 7E11 reactivity was reported in only half of their renal and urothelial cancers (15 of 30) and 3 of 19 colon carcinomas. In the present study, mAbs J591, J415, J533, and E99 demonstrate reactivity with tumor vasculature in all 23 nonprostate carcinomas tested. Some of the increased reactivity seen herein may represent the benefit of studying frozen as compared to paraffin sections. Within this study, when comparing mAbs J591, J415, J533, and E99 to 7E11 using a constant tissue preparation (frozen sections), we found stronger reactivity with mAbs J591, J415, J533, and E99 than with 7E11. The most likely explanation for the generally stronger reactivity seen with these new mAbs is that they were selected for, among other features, strong immunohistochemical reactivity. We have not studied the immunohistochemical reactivity of mAbs J591, J415, J533, and E99 on paraffin sections.

The initial study with 7E11 (1) indicated reactivity to fixed, but not viable, LNCaP cells later explained by epitope mapping studies indicating the 7E11 epitope to be intracellular (12). A more recent study by Troyer et al. (13) studying ultrathin sections by IEM demonstrated 7E11 reactivity on the cytoplasmic aspect of LNCaP...
El B In @ 0.5

Epitope mapping of the four present mAbs demonstrates that J591, J533, and E99 each bind to a single epitope (PSMACX@I), whereas J415 binds to a different, noncompeting site (PSMAexa). This will allow the development of a "sandwich" assay to determine the presence and measure the level of PSMA in serum, which is an area of some current controversy (14, 16).

By allowing the study of viable cells, these mAbs will be useful for studies of PSMA function and PCa cell biology. Recent work indicates that PSMA has glutaminase (19, 20) activity. Studies are under way to determine whether mAbs to PSMACxtI and/or PSMACX@2 can block this enzymatic activity and, if so, the effect of such a blockade on normal and neoplastic prostate physiology.

Given prior understanding of PSMA specificity and expression and the established ability of 7E1 1/CYT-356 to localize in vivo to a substantially less available epitope, one would anticipate the likelihood that these new mAbs might demonstrate significantly improved in vivo targeting for imaging and therapy. The immunoreactivity of these mAbs to vascular endothelium of a wide variety of cancers may significantly broaden their in vivo utility.

Acknowledgments

We thank Dr. John Wei for assistance with cultures of fresh prostate epithelial cells, Clarence Williams for the preparation of MHA indicator cells, and Troyer et al. (13) for confirming that 7E1 1 reacts with viable LNCaP cells.

Fig. 5. Competitive binding assay of biotinylated mAbs. PSMA was first captured by 7E11, then unlabeled blocking mAb was added, followed 1 h later by the indicated biotinylated mAb: 0.3 μg/ml J591-biotin (A); 1.25 μg/ml J533-biotin (B); 0.2 μg/ml J415-biotin (C); and 1.25 μg/ml E99-biotin (D). Each unlabeled mAb blocks its biotinylated counterpart (positive control); mAb 156 (to PSP) did not block (negative control). mAbs J591, J533, and E99 compete with each other for binding, whereas J415 does not.
