Abstract

Epidemiological and laboratory studies suggest that nonsteroidal anti-inflammatory drugs reduce the risk of colon cancer and that the inhibition of colon carcinogenesis is mediated through modulation of prostaglandin production by cyclooxygenase (COX) isozymes (COX-1 and -2). Overexpression of COX-2 has been observed in colon tumors; therefore, specific inhibitors of COX-2 activity could potentially serve as chemopreventive agents. Our recent study indicated that celecoxib (SC-58635), a specific COX-2 inhibitor, suppressed colonic aberrant crypt foci formation induced by azoxymethane in rats and led us to investigate more specifically the chemopreventive potential of this compound using colon tumors as end points. Five-week-old male F344 rats were fed the control diet (modified AIN-76A) or an experimental diet containing 1500 ppm celecoxib. Two weeks later, all animals except those in the saline-treated groups received s.c. injections of azoxymethane (15 mg/kg of body weight) once weekly for 2 weeks. All groups were kept on their regimen until the experiment was terminated, 50 weeks after carcinogen treatment. Colon tumors were evaluated histopathologically. Remarkably, dietary administration of celecoxib inhibited both incidence and multiplicity of colon tumors by about 93% and 97%, respectively. It also suppressed the overall tumor burden by more than 87%. The degree of tumor inhibition was more pronounced with celecoxib than it was with previously evaluated nonsteroidal anti-inflammatory drugs. The results of this study provide evidence, for the first time, that a specific COX-2 inhibitor, celecoxib, possesses strong chemopreventive activity against colon carcinogenesis.

Introduction

Large bowel cancer is one of the leading causes of cancer deaths in Western countries, including North America (1). Several epidemiological studies suggest an inverse association between the risk of colon cancer and intake of NSAIDs, especially aspirin (2-4). Laboratory animal assays have demonstrated colon tumor inhibition by several NSAIDs, including aspirin, piroxicam, sulindac, sulindac sulfone, and ibuprofen, to name a few (5-8). Clinical studies in patients with familial adenomatous polyposis indicate that administration of sulindac causes a regression and prevents recurrence of polyps, the precursor lesion of colon cancer (2). Although the precise mechanism by which NSAIDs inhibit colon carcinogenesis is not clear, it is often attributed to specific or non-specific inhibition of arachidonic acid metabolism via COX enzymes, which, in turn, modulate eicosanoid production and affect cell proliferation, tumor growth, and immune responsiveness (9). The levels of PGs and COX activities are elevated in tumors (10); therefore, suppression of PG production via COX activity by the administration of NSAIDs provided a mechanistic strategy for the chemoprevention of colon cancer. In addition to inhibition of PG production, sulindac, a NSAID, also increases apoptosis in chemically induced colon tumors (11) and in Min mice (12). Accumulating evidence indicates that conversion of arachidonic acid to PGs is catalyzed by two isozymes, COX-1 and COX-2. Both have been shown to be present in colon tumors of rodents and humans (10, 13-16). COX-1 is believed to be constitutively expressed in most tissues that generate PGs for normal physiological function. Thus, the expression of this isozyme does not fluctuate due to stimuli, whereas COX-2 expression can be induced by various agents, including growth factors and tumor promoters (17-19). Also, prolonged administration of NSAIDs has been associated with side effects, such as gastrointestinal ulceration and renal toxicity. These potential toxicities of NSAIDs are manifested by the inhibition of the constitutive enzyme, COX-1 (20-22). A study by Tsuji and DuBois (23) indicated that intestinal epithelial cells overexpressing the COX-2 gene develop altered adhesion properties and resist undergoing apoptosis; these changes are reversed by treatment with NSAIDs, suggesting that overexpression of COX-2 may alter the development of neoplasms in the intestine. That commonly used NSAIDs inhibit the activity of both isozymes of COX, which accounts for their therapeutic and adverse side effects, and that sensitivity of recombinant COX-2 toward inhibition by NSAIDs is different from that of COX-1 (24, 25) make it likely that specific inhibitors of COX-2 can serve as chemopreventive agents in colorectal cancer without side effects (23). Oshima et al. (16) demonstrated that COX-2 gene knockout and MF Tricyclic, a COX-2 inhibitor, reduced the number and size of the intestinal polyps in Apc<sup>−/−</sup> knockout mice. Celecoxib (SC-58635) is a novel, specific inhibitor of COX-2 with significant anti-inflammatory and analgesic properties (26-28). In a previous study, we reported that celecoxib suppressed preneoplastic lesions in the colon of rats (29); therefore, we designed a preclinical efficacy study that would more fully evaluate this compound for its chemopreventive properties, using colon tumor formation as an end point. This double-blind study was designed to investigate the chemopreventive potency of celecoxib on AOM-induced colon carcinogenesis in male F344 rats. The ultimate goal of this study was to determine whether this compound is an effective chemopreventive agent against chemically induced colon carcinogenesis in preclinical efficacy studies and, eventually, in human clinical trials.

Materials and Methods

Animals, Diets, Carcinogen, and Chemopreventive Agent. AOM (CAS: 25843-45-2) was purchased from Ash Stevens (Detroit, MI). Celecoxib (SC-58635; 4-[5-(4-methylphenyl)-3-(trifluoromethyl)-1H-pyrazol-1-yl]benzenesulfonamide; Fig. 1) was kindly supplied by Searle Research and Development (St. Louis, MO). Weanling male F344 rats were purchased from Charles River Breeding Laboratories (Kingston, NY). All ingredients of the semipurified diet were obtained from Dyets Inc. (Bethlehem, PA). The experimental diet was prepared weekly by mixing celecoxib with modified AIN-76A diet, and it was...
CHEMOPREVENTION OF COLON CANCER BY COX-2 INHIBITOR

Experimental Procedure. At 5 weeks of age, the rats were fed either control diet (modified AIN-76A) or experimental diet containing 1500 ppm celecoxib. At 7 weeks of age, all animals except those intended for saline treatment received s.c. injections of AOM (15 mg/kg body weight) once weekly for 2 weeks. The rats were then maintained on control or experimental diets until termination of the experiment. Body weights were recorded weekly for the first 8 weeks and then every 4 weeks. Animals were monitored daily for their general health. The experiment was terminated 50 weeks after the second AOM treatment, at which time all animals were killed by CO2 euthanasia. After laparotomy, the entire stomach and intestines were resected and opened longitudinally, and the contents were flushed with normal saline. Using a dissection microscope, small and large intestinal tumors were noted grossly for their location, number, and size. The length, width, and depth of each tumor were measured with calipers. Tumor volume was calculated using the formula $V = \frac{L \cdot W \cdot D}{2}$ (31), where $V$ is volume, $L$ is length, $W$ is width, and $D$ is depth. All other organs, including kidneys and liver, were also grossly examined under the dissection microscope for any abnormalities. Tumors were fixed in 10% buffered formalin, embedded in paraffin blocks, and processed for histological evaluation by routine procedures with H&E staining. The stained sections were examined for tumor types according to the classification of Pozharisski (32), with minor modifications.

Statistical Analysis. Body weights, tumor incidence, tumor multiplicity, and tumor volume were compared between the animals fed the control and the celecoxib diet. Tumor incidence, expressed as percentage of tumor-bearing animals, was analyzed by Fisher’s exact probability test, whereas tumor multiplicity, expressed as the mean number of tumors per animal, was analyzed by the unpaired Welch’s t test, accounting for unequal variance. Differences in body weights and tumor volume between the groups were analyzed by Welch’s t test and ANOVA. Differences were considered statistically significant at $P < 0.05$.

Results

General Observations. The body weights of animals treated with vehicle or AOM and fed the control diet or celecoxib, respectively, were comparable throughout the study (Table 1). In saline-treated animals, chronic administration of celecoxib did not produce any

Colon Tumor Data. Table 2 summarizes AOM-induced colon tumor incidence (percentage tumor-bearing animals) and colon tumor multiplicity (number of tumors per animal). All tumors were classified as adenomas and adenocarcinomas. Adenocarcinomas were further classified as invasive and noninvasive carcinomas, based on depth of invasion. There were no tumors in saline-treated animals given the control diet or 1500 ppm celecoxib. Administration of celecoxib suppressed the total colon tumor incidence (adenomas and adenocarcinomas) by about 93% (P < 0.000001) and total tumor multiplicity by 97% (P < 0.000001). Importantly, only 2 of 36 (6%) rats that had received celecoxib showed tumors in the colon, whereas 29 of the rats (85%) treated with AOM and fed control diet showed tumors in the colon. None of the animals administered celecoxib had developed colon adenomas, whereas three rats (9%) in the group without celecoxib administration showed adenomas in the colon. Celecoxib inhibited the incidence of both noninvasive and invasive adenocarcinomas of the colon by about 93% (P < 0.0001) and 96% (P < 0.000001), respectively. Also celecoxib inhibited the multiplicity of both noninvasive and invasive adenocarcinomas of the colon by 95% (P < 0.001) and 98% (P < 0.000001), respectively. Results summarized in Table 3 demonstrate that colon tumor volume was significantly reduced in rats given celecoxib as compared to that of the control group (P < 0.01; 87%).

Discussion

Because prolonged administration of NSAIDs has been associated with gastrointestinal ulceration and renal toxicity and because several commonly used NSAIDs such as aspirin, sulindac, piroxicam, and indomethacin have very little or no selectivity for inhibiting COX-1 or COX-2 activity, more specific yet minimally toxic inhibitors of COX-2 as chemopreventive agents need to be developed. The major aim of this study was to investigate the chemopreventive efficacy of a specific COX-2 inhibitor, celecoxib, against development of colon cancer. Selection of this particular agent for the chemopreventive efficacy study was based on our earlier observation that celecoxib inhibited formation of colonic aberrant crypt foci, which are early preneoplastic lesions with the potential for malignancy in the colon (29). The outcome of this study is of great interest because it shows, for the first time, that celecoxib, a specific COX-2 inhibitor, dramatically suppresses the colonic tumorigenesis in terms of tumor incidence, multiplicity, and burden. It is also noteworthy that the degree of inhibition of colon carcinogenesis in rats administered celecoxib exceeded that seen with NSAIDs, including aspirin, ibuprofen, sulindac, and piroxicam (tumor inhibitions of 40, 45, 55, and 70%, respectively), which we had evaluated previously for their chemopreventive potency in similar experimental design (5-8). Long-term administration of celecoxib at 1500 ppm did not induce any toxic side effects, such as body weight loss, gastrointestinal ulceration, or bleeding. It is also noteworthy that a pilot endoscopic study showed no difference in gas-troduodenal mucosa damages between celecoxib group and placebo group (28). Thus, specific inhibitors of COX-2 that induce very few toxic side effects but have increased chemopreventive potency may provide a new and effective approach to the chemoprevention of colon cancer.

Although the precise mechanism by which celecoxib inhibits colon carcinogenesis is not certain, the available data support the hypothesis that arachidonic acid metabolism is altered through COX activity, thereby reducing eicosanoid production (33). Various findings suggest that PGs have a role in the pathogenesis of colon cancer because they modulate several signal transduction pathways (10, 17, 23). Several studies have also demonstrated the role of COX-2 metabolites, particularly prostaglandin E2, in colon tumor promotion (33, 34). Our recent study indicated that increased levels of immunoreactive COX-2 are present not only in colon tumors but also in as yet tumor-free colon mucosa, as early as 1 week after carcinogen administration (35). Oshima et al. (16) indicated that induction of COX-2 is a very early event in the sequence of polyp formation to colon carcinogenesis. This study demonstrated that administration of celecoxib produced colon tumor-inhibitory effects, both at the initiation phase and during promotion and progression phases of carcinogenesis. The increased level of COX-2 protein may result in elevated PG levels in these tumors. Several studies have shown that COX-2 but not COX-1 gene expression and protein expression are markedly elevated in most human colorectal cancers, as compared with accompanying normal mucosa (10, 13, 14). This is also true for AOM-induced colon cancer in the rat model (15) and in Min mice (12). Dubois et al. (17, 23) have demonstrated that the COX-2 gene is induced following growth factor or tumor promoter stimulation of rat intestinal epithelial cells and that COX-2 overexpression is linked to changes in cellular adhesion and inhibition of apoptosis. Thus, the metabolic products derived from its catalytic formation appear to play a role in tumor promotion and progression.

In conclusion, administration of celecoxib, a specific COX-2 inhibitor, suppressed the incidence and multiplicity of colon tumors and the total tumor burden induced by AOM in male F344 rats. The degree of inhibition was more pronounced with celecoxib than it was with NSAIDs, which were evaluated using similar protocols. These results suggest that celecoxib could serve as an effective chemopreventive agent with low toxicity against colon cancer development in humans.
