ABSTRACT

The development of new therapeutic strategies is essential for the management of gliomas, one of the most malignant forms of cancer. We have shown previously that the growth of the rat glioma C6 cell line is inhibited by psychoactive cannabinoids (I. Galve-Roperh et al., Nat. Med., 6: 313–319, 2000). These compounds act on the brain and some other organs through the widely expressed CB₁ receptor. By contrast, the other cannabinoid receptor subtype, the CB₂ receptor, shows a much more restricted distribution and is absent from normal brain. Here we show that local administration of the selective CB₂ agonist JWH-133 at 50 µg/day to Rag-2⁻/⁻ mice induced a considerable regression of malignant tumors generated by inoculation of C6 glioma cells. The selective involvement of the CB₂ receptor in this action was evidenced by: (a) the prevention by the CB₂ antagonist SR144528 but not the CB₁ antagonist SR141716; (b) the down-regulation of the CB₂ receptor but not the CB₁ receptor in the tumors; and (c) the absence of typical CB₁-mediated psychotropic side effects. Cannabinoid receptor expression was subsequently examined in biopsies from human astrocytomas. A full 70% (26 of 37) of the human astrocytomas analyzed expressed significant levels of cannabinoid receptors. Of interest, the extent of CB₂ receptor expression was directly related with tumor malignancy. In addition, the growth of grade IV human astrocytoma cells in Rag-2⁻/⁻ mice was completely blocked by JWH-133 administration at 50 µg/day. Experiments carried out with C6 glioma cells in culture evidenced the internalization of the CB₂ but not the CB₁ receptor upon JWH-133 challenge and showed that selective activation of the CB₂ receptor signaled apoptosis via enhanced ceramide synthesis de novo. These results support a therapeutic approach for the treatment of malignant gliomas devoid of psychotropic side effects.

INTRODUCTION

Cannabinoids, the active components of Cannabis sativa and their derivatives, exert a wide spectrum of central and peripheral actions, such as analgesia, anticonvulsion, anti-inflammatory, and alleviation of both intraocular pressure and emesis. These effects are mediated by the activation of specific G protein-coupled receptors (1, 2). To date, two different cannabinoid receptors have been characterized and cloned from mammalian tissues: CB₁ (3) and CB₂ (4). The central and peripheral effects of cannabinoids rely on CB₁ receptor activation. This receptor is found in high levels in the central nervous system, where it mediates cannabinoid psychoactivity, and is also present in peripheral nerve terminals, as well as in extra-neural sites, such as testis, uterus, vascular endothelium, eye, spleen, and tonsils (1–6). By contrast, the CB₂ receptor is believed to be solely expressed in cells and organs of the immune system and is unrelated to cannabinoid psychoactivity (1, 2). The discovery of a family of endogenous ligands of cannabinoid receptors, the so-called endocannabinoids (7–9), together with their specific mechanisms of synthesis and inactivation (10, 11), have focused much attention on cannabinoids during the last few years.

Marijuana and its derivatives have been used in medicine for many centuries, and nowadays, there is a renaissance in the study of the therapeutic effects of cannabinoids, which constitutes a widely debated issue with ample scientific and social relevance. Ongoing research is determining whether cannabinoid ligands may be effective agents in the treatment of pain (12, 13), glaucoma (14), neurodegenerative disorders such as Parkinson’s disease (15) and multiple sclerosis (16), and the wasting and emesis associated with AIDS and cancer chemotherapy (14). In addition, cannabinoids might be potential antitumoral agents because of their ability to inhibit the growth of various types of cancer cells in culture (17–19). Moreover, in laboratory animals, cannabinoids induce the regression of gliomas, one of the most malignant forms of cancer whose current treatment in patients is usually ineffective or just palliative (20). This growth-inhibiting effect was exerted by two psychoactive cannabinoids, namely THC, the main active component of marijuana, and WIN-55,212-2, a nonselective synthetic cannabinoid agonist, pointing to the involvement of cannabinoid receptors (20). It would be desirable, however, that cannabinoid-based therapeutic strategies were devoid of typical CB₁ receptor-mediated psychotropic side effects. Hence, the recent synthesis of selective CB₂ agonists (21, 22) opens a very attractive clinical possibility. The present work was therefore undertaken to test: (a) if gliomas, including those of human origin, express functional CB₂ receptors; (b) if selective CB₂ receptor activation exerts an antitumoral action in vivo; and (c) what may be the mechanism of that potential CB₂-mediated antitumoral action.

MATERIALS AND METHODS

Materials. JWH-133 was prepared in Dr. J. W. Huffman’s laboratory (22). SR141716 and SR144528 were kindly given by Sanofi Recherche (Montpellier, France). The anti-CB₁ receptor antibody (raised against residues 1–14 of the rat CB₁ receptor) was kindly given by Dr. A. Howlett (North Carolina Central University, Durham, NC). The anti-CB₂ receptor antibody (raised against residues 20–33 of the human CB₂ receptor) was from Cayman Chemicals (Ann Arbor, MI). The Cy3-conjugated antirabbit IgG was from Amersham-Pharmacia (Buckinghamshire, United Kingdom). WIN-55,212-2 was from Sigma Chemical Co. (St. Louis, MO).

Glioma Cell Culture and Death. The rat glioma C6 line was cultured as described before (18). Cell viability was determined by the 3-4,5-dimethyl-thiazol-2,5-diphenyltetrazolium bromide thiazol blue test (18). Apoptosis was determined by TUNEL staining. After cannabinoid treatment, C6 glioma cells were washed with PBS, fixed in PBS supplemented with 4% paraformaldehyde.
and 5% sucrose for 15 min, and permeabilized with 0.05% Triton X-100 in PBS, and TUNEL analysis was performed as described before (20). Human tumor cells were prepared from a grade IV astrocytoma. The biopsy was digested with collagenase (type 1a) in DMEM at 37°C for 90 min, the supernatant was seeded in DMEM containing 15% FCS and 1 mM glutamine, and cells were inoculated in the animals after two passages.

**Antitumoral Action of Cannabinoids in Vivo.** Tumors were induced in mice deficient in recombinant activating gene 2 (Rag-2−/−), which lacks mature T and B cells (23), by s.c. flank inoculation of 5 × 10^6 tumor cells (either C6 glioma cells or human astrocytoma cells) in PBS supplemented with 0.1% glucose. When tumors had reached an average volume of 250 mm^3 (range, 200–300 mm^3), animals were assigned randomly to various groups and injected intratumorally with C6 glioma cells or 25 (human astrocytoma cells) days with vehicle or 50 μg of cannabinoid ligand (JWH-133, WIN-55,212-2, SR141716, and/or SR144528) per day in 100 μl of PBS supplemented with 5 mg/ml defatted and dialyzed BSA. Tumors were measured with external caliper, and volume was calculated as (4/3)π × (width/2)^2 × (length/2).

**Motor Activity.** Motor activity (ambulation, rearing, and time of inactivity) was tested after intratumoral injection to C6-cell glioma-bearing mice, exactly under the aforementioned conditions, with vehicle or 50 μg of cannabinoid agonist (JWH-133 or WIN-55,212-2) in an open field (30 × 30 cm, divided into 16 squares of equal size) for 15 min. Animals were not habituated previously to the open field.

**Immunofluorescence Analysis of Cannabinoid Receptors.** After cannabinoid treatment, cells were washed with PBS and fixed in cold acetone for 5 min. Immunostaining was performed according to Hashi et al. (24). Cells were incubated with the anti-CB1 or anti-CB2 receptor antibodies (1:500) in the latter buffer for 3–4 h at room temperature and overnight at 4°C in a humid chamber. After washing with PBS, cultures were further incubated for 90 min with a Cy3-conjugated antirabbit IgG (1:800), washed first with PBS and then with 50 mM Tris-HCl (pH 7.4), and mounted with 50% glycerol. Preparations were analyzed with a Zeiss confocal laser-scanning microscope (excitation 550 nm, emission 565 nm). There was no labeling when the primary antibody was omitted (data not shown). In other experiments, 40-μm cryostat sections from C6 glioma-cell tumors were similarly treated after fixation with 4% paraformaldehyde in 0.1 M sodium phosphate buffer (pH 7.4) for 30 min. Finally, immunostaining was also performed in 5-μm sections of human astrocytomas (from the files of the Department of Pathology of Clinica Puerta de Hierro and with informed consent from each subject) pre-embedded in paraffin after deparaffinization of the sections. Deparaffinized sections were incubated in DAKO sodium citrate buffer in a pressure cooker for 4 min, and immunohistochemical staining with the anti-CB1 and CB2 receptor antibodies was evaluated using the avidin-biotin/ peroxidase technique in a Horizon Dako (Mesip program) automated immunohistochemical stainer, according to the manufacturer instructions.

**Western Blot Analysis of Cannabinoid Receptors.** Particulate cell or tumor fractions were subjected to SDS-PAGE, and proteins were transferred from the gels onto polyvinylidene fluoride membranes. The blots were incu-...ted b... the g...s...t...e...m...t...a...s...e...d...t...o...g...l...u...t...i...n...e...n...t...s...a lifted with the signal in the plasma membrane and the cytoplasm detected for both receptors in cultured cells. Exposure to cannabinoid agonists is known to induce internalization of cannabinoid receptors (1, 2, 24). Likewise, upon WIN-55,212-2 exposure, CB1 and CB2 receptors were examined by immunofluorescence experiments. As shown in Fig. 2a (A), a quite homogenous signal in the plasma membrane and the cytoplasm was detected for both receptors in cultured cells. Exposure to cannabinoid agonists is known to induce internalization of cannabinoid receptors (1, 2, 24). Likewise, upon WIN-55,212-2 exposure, CB1 and CB2...
Simultaneously. Of interest, the extent of CB2 receptor expression was maintained from tumor-bearing mice. CB1 receptor expression was not directed by JWH-133, whereas SR144528 inoculation significantly increased it (Fig. 2). CB1 receptor expression remained unaffected by this cannabinoid (Fig. 2). Cannabinoid receptor immunoreactivity was also detected in C6-cell gliomas obtained from tumor-bearing mice. CB1 receptor expression was not significantly affected by JWH-133 and SR144528 administration, but in SR141716-treated tumors, a slight increase in the labeling was noted (Fig. 2). By contrast, CB2 receptor expression was reduced by JWH-133, whereas SR144528 inoculation significantly increased it and blocked the JWH-133 effect. SR141716 did not significantly affect the labeling (Fig. 2). These observations are in agreement with the well-known tolerance that occurs after chronic cannabinoid administration (1, 2) and further support the notion that CB2 receptors are functional in C6 glioma cells, JWH-133 being a highly selective CB2 agonist in our experimental system.

Regression of Human Astrocytomas in Vivo by Selective CB2 Receptor Activation. The presence of CB1 and CB2 receptors was analyzed by immunohistochemistry in biopsies from human astrocytomas of low (grades I–II) and high (grades III–IV) malignancy. High malignancy tumors were diagnosed in all cases as pure astrocytomas, whereas some of the low malignancy tumors were mixed oligoastrocytomas. However, no differences were observed in the distribution of cannabinoid receptors between pure and mixed tumors (data not shown). A full 70% (26 of 37) of the total tumors analyzed expressed measurable levels of cannabinoid receptors (i.e., CB1 and/or CB2). Among them, a similar percentage of low malignancy (4 of 12) and high malignancy tumors (6 of 25) expressed CB1 and CB2 receptors simultaneously. Of interest, the extent of CB1 receptor expression was related with tumor malignancy. Thus, as shown in Table 1, the proportion of grade IV astrocytomas showing high/very high CB2 immunoreactivity doubled that of grades I–III tumors. Moreover, CB2 receptor expression was markedly enhanced in grade IV astrocytomas compared with CB1 receptor expression.

Given the inhibition of C6-cell glioma growth by selective CB2 receptor activation (Fig. 1), we evaluated the effect of JWH-133 treatment on the growth of highly malignant (grade IV) human astrocytoma cells in vivo. Immunofluorescence microscopy and Western blot analyses evidenced the expression of the CB2 receptor in the inoculated cells (Fig. 2). This particular tumor also expressed the CB2 receptor (data not shown). Of interest, JWH-133 administration completely blocked the proliferation of the human astrocytoma (Fig. 2). Examples of tumor-bearing mice and of dissected tumors after cannabinoid treatment for 25 days are shown in Fig. 2.

Selective CB2 Receptor Activation Signals Apoptosis of C6 Glioma Cells via Ceramide Synthesis de Novo. We have shown previously that THC-induced apoptosis of C6 glioma cells relies on the sustained generation of the proapoptotic lipid ceramide (20, 29). To obtain further evidence for the specificity of the JWH-133 antitumoral action, experiments were carried out with L-cycloserine, a selective competitive inhibitor of SPT, the enzyme which catalyzes the pace-setting step of ceramide synthesis de novo (30). As shown in Fig. 3, exposure to JWH-133 induced apoptosis of C6 glioma cells, and this effect was prevented by L-cycloserine. Moreover, L-cycloserine was able to suppress JWH-133-evoked SPT induction (Fig. 3). We also tested the effect of L-cycloserine on JWH-133-induced ERK activation, as ERK seems to be the downstream target of ceramide in THC-evoked apoptosis of C6 glioma cells (20, 29). Thus, blockade of ceramide synthesis de novo with L-cycloserine abrogated JWH-133-induced ERK activation (Fig. 3), indicating that JWH-133, like THC, signals apoptosis via ceramide synthesis de novo and ERK activation.

DISCUSSION

Recent studies have dealt with the antiproliferative effect of cannabinoids on different transformed cells. However, this property of cannabis compounds was first reported 25 years ago by Munson et al. (31), who showed that cannabinoids may inhibit the growth of Lewis lung adenocarcinoma, B-tropic Friend leukemia virus-induced splenomegaly, and L1210 leukemia cells in vivo. Although these observations were actually promising, further investigations were not performed on this area until a few years ago. Nowadays, there are data demonstrating that cannabinoids inhibit the growth of transformed
neural, breast, and prostate cells in culture (32) and induce the regression of gliomas in vivo (Ref. 20 and the present study). The case of gliomas is of particular interest because they are one of the most malignant forms of cancer, resulting in the death of affected patients within months after diagnosis. Conventional therapies, including surgery, radiotherapy, chemotherapy, and immunotherapy, are usually ineffective or just palliative (33, 34). The most recent strategies for glioma treatment are focused on gene therapy, but no trial performed

Fig. 2a. Immunofluorescence analysis of cannabinoid receptor dynamics in cultured glioma cells and in gliomas. Images of representative experiments are shown. Similar results were obtained in three other experiments for each experimental condition. In A, C6 glioma cells were cultured for 30 min in the absence or presence of 100 nM JWH-133 or WIN-55,212-2. B, C6-cell gliomas. Mice were treated as in Fig. 1 for 8 days, tumors were dissected, and immunomicroscopy analysis was performed. Abbreviations as in Fig. 1. Fig. 2b. Regression of human astrocytomas in vivo upon selective CB2 receptor activation. A, example of CB2 receptor expression in a grade IV human astrocytoma (HA) as assessed by immunomicroscopy analysis of a tumor section and of cells derived from the tumor. Western blot analysis of the tumor was also performed using C6 glioma cells as a control. In B, cells from the tumor shown in A were injected s.c. in mice. When tumors had reached the desired size (day 0), animals were treated with either vehicle (○) or JWH-133 (●) for 25 days (n = 6 for each experimental group). C, examples of s.c. gliomas in the flank of mice (top panel) and after dissection (bottom panel) after treatment with vehicle or JWH-133 (JWH) for 25 days.
thus far has been significantly successful (33–35). It is therefore essential to develop new therapeutic strategies for the management of gliomas and most likely to combine some of them to obtain significant clinical results. One of these alternative therapeutic approaches might be on the basis of the use of nonpsychoactive cannabinoid ligands, because these compounds induce apoptosis in vitro and inhibition of tumor growth without significant collateral effects in vivo. Because of the current inability to kill target glioma cells with sufficient efficacy to obtain significant tumor regression in the clinical practice, the combined use of drugs that inhibit tumor growth with cytotoxic approaches may be envisaged as the most feasible anticancer strategy in the near future. Of interest, cannabinoid apoptotic action relies on the generation of ceramide, a lipid second messenger that may have antitumoral properties either alone (36) or in combined therapies (37).

We are nevertheless aware that under certain circumstances, cannabinoids may be immunosuppressive compounds by acting on immune organs and cells via CB2 receptors, and this would be expected to inhibit host antitumor immunity. As a matter of fact, Zhu et al. (38) have recently reported that i.p. THC injection to immune-competent mice for 4–6 weeks leads to an accelerated growth of tumor implants in two different murine lung cancer models. This effect, although not evidenced in the former report by Munson et al. (31), was shown to rely on the CB2-dependent inhibition of the capacity of antigen-presenting cells and T cells to generate alloreactivity (38). It is therefore possible that cannabinoids exert a dual effect on tumor growth, i.e., a direct antiproliferative effect (Ref. 20 and the present study) and an indirect growth-enhancing effect via inhibition of immunogenicity (38). Factors such as the route of drug administration (local versus systemic), the timing of drug delivery (short-term versus long-term treatment), and the intrinsic capacity of a particular tumor cell to respond to cannabinoids (e.g., presence versus absence of cannabinoid receptors) might determine the balance between tumor progression and regression. In any event, the present study, together with our previous observations (20), shows that the antitumoral action of cannabinoids on gliomas may be exerted either via the CB1 receptor or via the CB2 receptor. The attractive possibility of finding cannabinoid-based therapeutic strategies for neural diseases devoid of undesired CB1-mediated psychotropic side effects is also opened by the possible implication of the CB2 receptor in the control of pain presentation (39, 40) have reported for myeloid cell growth and transformation during leukemogenesis.
