Abstract
Cancer chemopreventive activity of sulforaphane has been predominantly associated with its ability to induce phase II detoxification enzymes. In the present study, novel targets of sulforaphane were identified and characterized using a proteomics approach. Two-dimensional gel electrophoresis and mass spectrometry were used to produce protein profiles of human colon adenocarcinoma Caco-2 cells treated with 5 μmol/L sulforaphane for 48 h and control cells (0.05% DMSO). Gel comparisons showed the down-regulation to undetectable level of the serotonin receptor 5-HT3 after sulforaphane treatment. In addition, Aldo-keto reductase and β-dopachrome decarboxylase were also differentially expressed in control and treated cell extracts. To elucidate two-dimensional gel findings, the neurotransmitter receptors 5-HT3, 5-HT1A, and 5-HT2C, and the serotonin reuptake transporter were analyzed using Western blotting. Results showed a decrease of neurotransmitter receptors in a dose-dependent manner after sulforaphane treatment. Moreover, after exposure of Caco-2 cells to sulforaphane, nicotinic acetylcholine receptor protein level was increased. These findings suggested a potential effect of sulforaphane on serotonin release. Activation of neurotransmitter receptors followed by initiation of cyclic AMP signaling might be crucial events in colon carcinoma progression. Thus, the effect of sulforaphane may help to elucidate signaling pathways serotonin-mediated in colon cancer and lead to development of potential novel therapeutic agents. [Cancer Res 2008;68(13):5487–91]

Introduction
Sulforaphane, an isothiocyanate found in cruciferous vegetables, has been widely studied as a chemopreventive agent (1). The most studied role of sulforaphane in chemoprevention is its ability to induce phase II detoxification enzymes. Experimental evidence suggests that sulforaphane is effective against many carcinogen-induced tumors through induction of phase II detoxification enzymes. Data from in vivo and in vitro studies showed that sulforaphane activates NF-E2 p45–related factor-2 transcription factor in binding antioxidant response elements in the promoter regions of target genes, thereby increasing cellular defenses against oxidative stress (2, 3). The anticarcinogenic activities of sulforaphane also include inhibition of phase I enzymes, protection against heterocyclic amine–induced DNA adduct formation, induction of apoptosis, and arrest of cell cycle progression (4–6). Recent studies suggest that sulforaphane suppresses lipopolysaccharide-induced cyclooxygenase-2 (COX-2) expression through the modulation of multiple targets in COX-2 gene promoter (7). COX-2 is a key enzyme catalyzing the rate-limiting step in the biosynthesis of prostaglandins from arachidonic acid. Accumulating evidence shows the overexpression of COX-2 in several epithelial carcinomas including bladder, breast, lung, esophagus, and colon (8, 9). Pathogenesis of colorectal cancer consists of a series of molecular and cellular events that become visible with adenomatous polyps formation (10). The current research is focused on assessing whether an increase in nutritional intake of sulforaphane may provide beneficial effects for colon cancer prevention. These levels are achievable, as data from a human intervention study showed that 2 hours after consumption of 100 grams standard and high-glucosinolate broccoli, plasma concentrations of sulforaphane and its metabolites reached 2.2 and 7.3 μmol/L, respectively (11). The purpose of this investigation was to identify and characterize novel targets of sulforaphane in human colon adenocarcinoma Caco-2 cells using relatively low concentrations of sulforaphane (5 μmol/L). In the present study, the novel effect of sulforaphane as modulator of neurotransmitter receptors was reported.

Materials and Methods
Materials. Human colon adenocarcinoma Caco-2 cell line was obtained from the European Collection of Cell Culture. Cell culture medium and supplements were purchased from Invitrogen. Sulforaphane (4-methylsulfinylbutyl isothiocyanate; purity, 97%) was purchased from LKT laboratories (Alexis Biochemicals). Reagents for two-dimensional gel electrophoresis were obtained from GE Healthcare, Bio-Rad, and Genomic Solutions (Proteomic Solutions). Antibodies for Western blotting were purchased from Alexam, Dako, and Santa Cruz. All other chemicals were purchased from Sigma and Roche Applied Science.

Cell culture and treatments. Cells were grown in DMEM. The cell culture medium was supplemented with 10% FCS, 1% penicillin/streptomycin, and 1% L-glutamine. Cell growth for proteomics studies was performed using 10-cm dishes under 5% CO2 in air at 37°C. Cells at passage 40 to 55 were treated with sulforaphane (5 μmol/L) for 48 h when they reached 50% of confluence. Sulforaphane was dissolved in DMSO. Control cells were treated with equal volume of DMSO (0.05%). For Western blotting studies, cells (2 × 104 per cm2) were seeded in 6-well plates and treated with sulforaphane (5, 10, and 20 μmol/L) for 48 h.

Protein extraction. Cells were washed twice with ice-cold PBS and then incubated for 30 min in the NP40 buffer [20 mmol/L Tris-HCl (pH 8), 150 mmol/L NaCl, 10% Glycerol, and 1% NP40] with addition of one tablet (in 10 mL buffer) of complete mini protease inhibitor cocktail (Roche) just before use. Cells were harvested by scraping and the homogenate was centrifuged at 13,000 g at 4°C for 15 min. The supernatants were collected and protein concentrations were determined using Bradford assay (Sigma) according to the manufacturer’s instructions. Aliquots of samples were stored at −80°C.

Two-dimensional gel electrophoresis. Protein extracts were desalted and concentrated to 4 mg/mL using a Biomax SMW Membrane Ultrafree 0.5 centrifugal filter (Millipore) at 12,000 g and 4°C before the two-dimensional gel procedure. For each sample, two biological and three technical replicate gels were run.
For Isoelectric focusing (IEF), the samples were prepared by mixing 200 μg protein with rehydration solution containing 7 mol/L urea, 2 mol/L thiourea, 2% (w/v) 3-[3-cholamidopropyl]dimethylammonio]-1-propanesulfonate hydrate, 18.2 mmol/L DTT, 2% pH 3-11 NL IPG buffer (GE Healthcare), and a trace of bromophenol blue (final volume, 440 μL). This was applied to a 24-cm Immobiline DryStrip pH 3-11 NL (GE Healthcare), and the strips allowed to rehydrate overnight at 20 °C. IEF was then performed on the IPGphor unit (GE Healthcare) for a total 44,800 V hours at 20 °C using the following conditions: Step and Hold at 500 V for 500 V hours, Gradient to 1,000 V over 800 V hours, Step and Hold at 500 V for 500 V hours, and Step and Hold at 8,000 V for 30,000 V hours. After IEF, the focused strips were frozen at −70 °C until required.

Before the second dimension, the focused strips were conditioned in filtered (0.45 μm) equilibration buffer, prepared as 5% SDS and 0.01% bromophenol blue in 0.122 mol/L Tris acetate (Tris Acetate Equilibration Buffer; Genomic Solutions), modified with 5 mg/mL final volume SDS, 360 mg/mL urea, and 300 mg/mL 99% glycerol. To reduce and alkylate cysteines, the strips were treated first with 8 mg/mL DTT in the equilibration buffer (9 mL; 30 min with gentle shaking) before being transferred into 25 mg/mL iodoacetamide in the equilibration buffer (9 mL; 30 min with gentle shaking). The equilibrated strips were layered onto home-cast 10% (v/v) Duracryl gels (26 × 21 cm; 1-mm thick) in the Investigator 2nd Dimension Running System (Genomic Solutions), and electrophoresis was carried out using a limiting power of 20 W per gel in a discontinuous buffer system [3 L cathode buffer (200 mmol/L Tris base, 200 mmol/L Tricine, and 14 mmol/L SDS) and 10.5 L anode buffer (25 mmol/L Tris/acetate buffer pH 8.3)].

**Gel imaging and analysis.** After electrophoresis, the gels were stained with Sypro-Ruby (Bio-Rad) according to the manufacturer’s instructions and imaged on the Pharus FX+ Imaging System (Bio-Rad) at 100-μm resolution using a 532-nm excitation laser and a 605-nm emission filter. Images were saved as 16-bit TIF files and analyzed by ProteomWeaver version 3.1 software (Definiens). Automatic matching with control gels was performed with base-paired normalization to compare the spot volume data.

**Protein identification.** Protein spots with altered levels of expression were excised from the gel using the ProPick excision robot (Genomic Solution), and in-gel trypsin-digested using a ProGest Protein Digester (Genomic Solutions). Gel plugs were first conditioned with two 20-min incubations in 200 mmol/L ammonium bicarbonate (ABC) in 50% acetonitrile (50 μL) followed by 10-min incubations with acetonitrile (50 μL). The gel plugs were then conditioned for 15 min with 25 mmol/L ABC (50 μL) followed by 10 min in acetonitrile (50 μL). A final 5-min incubation of acetonitrile (50 μL) preceded trypsin digestion at 37 °C (3 h) using 50 ng (5 μL each well) sequencing-grade porcine trypsin (Promega) dissolved in 25 mmol/L ABC. Digestion was stopped after 3 h, and peptides were extracted with formic acid (10%; 5 μL each tube). Tryptic digests were analyzed using an Ultraflex MALDI-ToF (matrix-assisted laser desorption/ ionization time-of-flight) instrument (Bruker Ltd.) at the Institute of Food Research/John Innes Centre Joint Proteomics facility. Proteins were identified from the peptide mass peak list by the Protein Mass Fingerprint technique using an offline copy of Mascot search tool (Matrix Science). SPtrEMBL was selected as sequence database; the taxonomy group searched was Homo sapiens; trypsin was selected as the reagent used for protein digestion with one allowed missed cleavage; the mass tolerance was 50 ppm; peptide masses were stated to be monoisotopic; carbamidomethyl modification of cysteine (as a fixed modification); and methionine oxidation (as a variable modification) were permitted. The results give a Probability Based Mowse Score, equal to −10XLog(P), where P is the probability that the observed match is a random event. Protein scores of >61 are considered statistically significant (P < 0.05) under the selected variables.

![Figure 1. Automatic matching between sulforaphane-treated (5 μmol/L; 48 h) and control gels. Coordinates for first-dimension (pI) and second-dimension (Mw) separation have been shown on the map. The spot numbers indicate the identified protein listed in Table 1. Blue spots, protein spots from the sulforaphane-treated gel. Red spot, protein spots from control gel. Boxes highlight the spot picking from specific areas of change on the individual gels: control (A) and sulforaphane-treated samples (B and C).](image-url)
Western blotting. Samples (60 µg of total cell protein extracts) were separated under reducing conditions on 10% polyacrylamide gels and transferred onto polyvinylidenedifluoride membranes (Bio-Rad) with a semidry transfer cell (Trans-Blot; Bio-Rad). Transfer was run at 15 V for 40 min. Membranes were blocked for 1 h at room temperature with Marvel fat-free milk powder (5%, w/v), Tween 20 (0.05%, v/v) in PBS. Antigenic bands were detected by exposing the membranes to primary antibodies (Abcam) overnight at 4°C [1:500 dilution for rabbit polyclonal antibodies to 5-HT3A and 5-HT1A receptors, and mouse monoclonal (ST51-2) to serotonin transporter (SERT); 1:1,000 dilution for rabbit polyclonal antibody to 5-HT2c receptor; 1:5,000 for goat polyclonal antibody to aldo-ketoreductase (AKR) and rabbit polyclonal to Nicotinic Acetylcholine Receptor (nAChR)] followed by incubation with secondary antibodies [1:10,000, horseradish peroxidase (HRP)-conjugated goat anti-rabbit or HRP-conjugated rabbit anti-goat; 1:1,000, polyclonal goat anti-mouse]. Signals were detected using an enhanced chemiluminescence kit (GE Healthcare) according to manufacturer’s instructions and β-actin level was determined as loading control.

### Results

Figure 1 shows the automatic matching between the two-dimensional gel of Caco-2 cells under sulforaphane treatment and the control. Boxes show the spots picking from the gels where significantly different protein expression was found. To validate protein identification analyses, two identically expressed spots were picked from control and sulforaphane-treated gels and successfully identified as Profilin-1 and Chaperonin 10. Characteristics of identified proteins are listed in Table 1 where protein scores of >61 are considered statistically significant (P < 0.05). Analyses of proteins differentially expressed showed as follows:

1. A spot was down-regulated to undetectable level after sulforaphane treatment. This spot was picked from control gels and identified as serotonin receptor 5-HT3. To confirm the two-dimensional gel findings, the effect of sulforaphane was determined by Western blot analysis using the antibody for 5-HT3A subunit serotonin receptor. As shown in Fig. 2, 5-HT3A (25 kDa) decreased in a dose-dependent manner, compared with control cells, after 48 hours of exposure to sulforaphane (5 µmol/L).

2. In sulforaphane-treated gels, a higher intensity protein spot was identified as AKR. Western blotting was used to study the effect of sulforaphane on AKR in Caco-2 cells treated with 5, 10, and 20 µmol/L sulforaphane for 48 h. Results showed a dose-dependent increase of AKR (35 kDa; Fig. 3), thereby confirming the two-dimensional gel analyses data.

3. In sulforaphane-treated gels, another protein spot identified as n-dopachrome decarboxylase showed a shift in isoelectric point. Using the NetPhos 2.0 Server (Denmark) to analyze the sequence of n-dopachrome decarboxylase, two phosphorylation sites were predicted with high confidence scores at Ser76 (score, 0.954) and Ser78 (score, 0.993) that may account for the shift on the two-dimensional gel.

As shown in Fig. 4, the effect of sulforaphane on neurotransmitter receptors was further investigated using Western blot analysis. Serotonin receptors 5-HT1A, 5-HT2C, and SERT were analyzed in Caco-2 cells treated with 5, 10, and 20 µmol/L sulforaphane for 48 h. Results showed a decrease of these proteins in a dose-dependent manner after sulforaphane treatment. In contrast, Western blot analyses showed a dose-dependent increase of nAChR expression after exposure to sulforaphane (Fig. 4D).

### Discussion

Sulforaphane is a potent cancer preventive agent, but its multiple mechanisms of action are not fully understood. In the present study, we showed for the first time that sulforaphane down-regulates the expression of three serotonin receptors in colon cancer Caco-2 cells. In addition, a decrease of SERT protein expression level was found in Caco-2 cells after treatment with

![Figure 2. Effect of sulforaphane on 5-HT3A subunit serotonin receptor](data:image/png;base64,iVBORw0KGgoAAAANSUhEUgAAAAQAAAAAIAAMAAADPzW0UAAAAGXRFWHRTb2Z0d2FyZQBBZG9iZSBJbWFnZVJlYWR5ccllPAAAAkFVPhcabAAAAAElFTkSuQmCC)
sulfuraphane. These results suggested a potential effect on serotonin release. Serotonin is synthesized from the enterochromaffin cells of the gastrointestinal tract to regulate gastrointestinal motility and epithelial function (12–14). Actions and responses between serotonin and a wide number of 5-HT receptors induce contraction of smooth muscle in the colon, secretion of chloride ions and emesis (15, 16), and cellular responses mediated by G proteins (17). Release of serotonin is regulated by complex neuronal and humoral inputs and also by stimulatory receptors (nicotinic acetylcholine, β-adrenergic, and muscarine) and inhibitory receptors (α-adrenergic, γ-aminobutyric acid, histamine H2-receptors, receptors for vasoactive intestinal polypeptide, and somatostatin; ref. 18). To investigate potential interactions of sulfuraphane with these stimulatory receptors, we found a dose-dependent up-regulation of the nAChR in Caco-2 cells after sulfuraphane treatment. Up-regulation of nAChR may be due to its constant turning off by sulfuraphane, as a decrease in neurotransmitters activity is believed to cause up-regulation of receptors (19).

The increased protein level of the stimulatory nAChR may also explain the down-regulation of serotonin reuptake by SERT and, finally, the down-regulation of serotonin receptors in response to signal for serotonin release.

The majority of serotonin receptors are G-protein–coupled receptors (GPCR; ref. 17), exception being the 5-HT3 receptor, which is a ligand-gated ion channel playing a role in emesis, anxiety, and intestinal smooth-muscle activation (20). GPCR is a large family of cell surface receptors that activate signal transduction pathways and cyclic AMP (cAMP) formation. Studies reported the sequence of events by which a signal molecule activates CAMP signaling. It has been shown that CAMP activates protein kinase A, which in turn phosphorylates Src and subsequently activates the Erk1/2 cascade (21). Activation of Erk1/2 has been associated with the up-regulation of COX-2 activity (22).

Previous studies showed that activation of neurotransmitter receptors has a role in colon cancer cells. Activation of β-adrenoceptors in colon cancer HT-29 cells increased cytosolic phospholipase A2 protein expression, COX-2 mRNA and protein expression, as well as prostaglandin E2 receptor (PGE2) release (23). Studies have also shown that activation of muscarinic M3 receptor up-regulated COX-2 and resulted in PGE2 production (24). In another study, activation of α7-nAChR (α7-nAChR) by nicotinestimulated HT-29 cell proliferation and adrenaline production (25).

In agreement with previous findings, proteomics data described here also revealed changes in expression of AKR (26) and D-dopachrome decarboxylase. AKR is abundantly expressed in the gastrointestinal tract and catalyzes the reduction of xenobiotics with broad substrate specificity. Interestingly, recent studies reported how members of AKR family efficiently reduced the antiemetic 5-HT3 receptor antagonist dolasetron (27, 28).

D-dopachrome decarboxylase is involved in the detoxification of the toxic quinine product of dopamine. Chung and colleagues (29) observed a similar effect of β-phenylethyl isothiocyanate on D-dopachrome decarboxylase in a proteomic investigation using human hepatoma HepG2 cells. Recent studies reported that sulfuraphane protects against compounds known to induce dopamine quinone production (30). Oxidation of dopamine, which is a precursor of adrenaline, to dopamine quinone causes oxidative stress.

In conclusion, this research suggests that a potential cancer preventive agent sulfuraphane regulates neurotransmitter receptors in Caco-2 cells. Understanding these effects of sulfuraphane could provide new insights into development of new therapies or therapeutic agents for colon cancer prevention.
