Abstract

Sphingosine-1-phosphate is a potent sphingolipid mediator of diverse processes important for brain tumors, including cell growth, survival, migration, invasion, and angiogenesis. Sphingosine kinase 1 (SphK1), one of the two isoenzymes that produce sphingosine-1-phosphate, is up-regulated in glioblastoma and has been linked to poor prognosis in patients with glioblastoma multiforme (GBM). In the present study, we found that a potent isotype-specific SphK1 inhibitor, SK1-I, suppressed growth of LN229 and U373 glioblastoma cell lines and nonestablished human GBM6 cells. SK-1 also enhanced GBM cell death and inhibited their migration and invasion. SK-1 rapidly reduced phosphorylation of Akt but had no significant effect on activation of extracellular signal-regulated kinase 1/2, another important survival pathway for GBM. Inhibition of the concomitant activation of the c-Jun-NH2-kinase pathway induced by SK1-I attenuated death of GBM cells. Importantly, SK-1 markedly reduced the tumor growth rate of glioblastoma xenografts, inducing apoptosis and reducing tumor vascularization, and enhanced the survival of mice harboring LN229 intracranial tumors. Our results support the notion that SphK1 may be an important factor in GBM and suggest that an isozyme-specific inhibitor of SphK1 deserves consideration as a new therapeutic agent for this disease.

Introduction

Glioblastoma multiforme (GBM) is the most prevalent and lethal type of primary central nervous system tumors with a median survival of 10 to 12 months, even after aggressive surgery, radiation, and advanced chemotherapy (1). Poor prognosis of patients with GBM has recently been correlated with elevated expression of sphingosine kinase type 1 (SphK1; refs. 2, 3), one of the SphK isoenzymes that generates the pleiotropic lipid mediator, sphingosine-1-phosphate (S1P). S1P has been implicated in the etiology of GBM due to its involvement in various cell processes particularly important for tumorigenesis, including growth, survival, invasion, angiogenesis, and metastasis (4–7). The biological effects of this serum-borne lipid are mainly mediated by a family of five specific G protein–coupled receptors, designated S1P1-5 (8). Of those, S1P1, S1P3, are expressed in the majority of human glioblastoma cell lines and are involved in S1P-mediated proliferation (4). Although S1P has no effect on matrix metalloproteinase secretion, it enhances glioblastoma cell adhesion and also stimulates their motility and invasiveness (9). Because S1P is present at high levels in brain tissue, it is possible that autocrine or paracrine signaling by S1P through its receptors enhances both glioma cell proliferation and invasiveness (10).

To explore the therapeutic implications of targeting SphK1 for treatment of GBM, we examined the effects of a newly developed isozyme-specific inhibitor of SphK1, SK1-I (11), and found that it inhibits growth of GBM in vitro and in vivo. Our results suggest that specific SphK1 inhibitors might be useful for treatment, either alone or in combination with advanced chemotherapeutic agents.

Materials and Methods

Cell culture. U373-MG and LN229 human glioblastoma cells (American Type Culture Collection) were cultured in DMEM supplemented with 5% FCS. Primary human nonestablished glioblastoma GBM6 cells were kindly provided by Dr. C. David James (University of California San Francisco, San Francisco, CA) and were passaged as subcutaneous tumors in nude mice and subcultured for 1 wk following isolation from tumors in media containing 2% FCS to prevent growth of contaminating rodent fibroblasts and then cultured in 5% FCS as described (12). LN229 cells were transfected with H2B-EGFP plasmid and stable colonies were isolated following selection with 1 mg/mL of G418. LN229-H2B-EGFP cells were passaged as tumors as described above.

Xenograft tumors. Adult male National Cancer Institute (NCI) nu/nu mice were purchased from NCI. All animal studies were conducted in the Animal Research Core Facility at Virginia Commonwealth University School of Medicine in accordance with the institutional guidelines. LN229 cells (1 × 10⁶) were injected in the flanks (four sites per mouse). Palpable tumors appeared in ~1 wk. Five days later, when tumors reached 3 to 4 mm in diameter, mice were randomly separated into two groups and injected i.p. with saline or SK1-I (10 mg/kg) every other day. Tumor measurements were made with calipers, and tumor volume was calculated using the formula: [π × (length in millimeters) × (width in millimeters)]/6. At the end of the experiment, the animals were euthanized and the tumors removed, fixed in formalin and embedded in paraffin, or frozen in liquid nitrogen.

Intracranial LN229 xenograft tumors. Adult female NCI nu/nu mice were anesthetized and LN229-H2B-EGFP cells (2.5 × 10⁶ in 1 μL PBS) were stereotactically implanted in the putamen region (1 mm anterior and 2.5 mm lateral to the Bregma at the depth of 3.5 mm at a rate of 0.1 μL/min). Mice were monitored for recovery until complete waking. Twenty days after implantation, mice were injected i.p. with SK1-I (20 mg/kg in PBS) every other day. Mice were observed daily following tumor implantation and were euthanized on reaching a moribund state.

In vitro assays. Immunoblotting, cell proliferation and cell death assays (13), SphK1 activity (11), and colony formation assays (14) were carried out following standard protocols as detailed previously.

Details about reagents, infection of cells with recombinant adenoviruses, and immunohistochemistry are presented as supplementary information.

Results

SK1-I potently inhibits growth and survival of human glioblastoma cells. Previous studies showed that S1P and SphK1, the kinase that produces it, play critical roles in growth and survival of glioblastoma cells (2, 4, 6). In agreement, down-regulation of SphK1 expression decreased growth of both U373 cells, which express mutated PTEN, and LN229 cells expressing wild-type PTEN, in serum-free medium as well as in the presence of serum, which greatly enhanced their growth (Fig. 1 A). Expression of SphK1 in these cells was drastically reduced by siRNA targeted to a specific sequence of SphK1 mRNA, as detected by Western blotting with a polyclonal anti-SphK1 antibody (Fig. 1 A). The greater sensitivity of U373 cells to down-regulation of SphK1 might be due to much lower SphK1 expression and enzymatic activity compared with LN229 cells (Fig. 1 B).

We recently described the first SphK1-specific inhibitor, SK1-I (11). SK1-I inhibited growth of both U373 and LN229 cells in a dose-dependent manner (Fig. 1 C). A significant inhibitory effect was observed at 3 μmol/L. SK1-I at 10 μmol/L strongly inhibited growth of U373 and LN229 cells cultured in the absence of serum (Fig. 1 C). SK1-I was less effective when cells were cultured in the presence of serum, which contains multiple growth factors and S1P. However, even in the presence of serum, within 2 to 4 days, there were severe reductions in cell numbers after treatment with 10 μmol/L SK1-I (Fig. 1 C).

SK1-I inhibits migration and invasion of glioblastoma cells. As S1P and SphK1 have been shown to regulate migration and invasion of glioblastoma cells (5, 7, 9, 15), and SphK1 regulates actin cytoskeletal dynamics (16) and lamellipodia formation (17), it was of interest to examine whether inhibition of SphK1 by SK1-I correlated with changes in reorganization of the actin cytoskeleton. Filamentous-actin (F-actin) was distributed across unstimulated U373 cells, as revealed by staining with Alexa 488–conjugated phalloidin (Supplementary Fig. S1 A). In response to phorbol 12-myristate 13-acetate the actin cytoskeleton underwent dramatic reorganization, and more F-actin was condensed at the leading edge within lamellipodia (Supplementary Fig. S1 A). In agreement with a previous study with human macrophages (16), down-regulation of SphK1 markedly reduced the number of actin-rich lamellipodia produced by treatment with PMA (Supplementary Fig. S1 A). Similarly, inhibiting SphK1 with SK1-I dramatically reduced PMA-stimulated F-actin reorganization at the leading edge as well as formation of lamellipodia and induced disassembly of filopodia (Supplementary Fig. S1 C and D).

These results support the notion that SphK1 activity is required for actin filament dynamics (16). Therefore, we next examined the effect of SK1-I on migration and invasion of glioma cells. Directed motility (chemotaxis) of U373 cells toward serum or epidermal growth factor (EGF) in Boyden chamber assays was reduced by SK1-I (Supplementary Fig. S2 A). Similarly, chemotaxis of LN229 cells, which show much greater rates of basal and stimulated migration toward serum and EGF than U373 cells, is also reduced by SK1-I (Supplementary Fig. S2 B).
significantly inhibited by SK1-I (Fig. 2A). SK1-I also drastically inhibited chemotaxis of LN229 cells toward lysophosphatidic acid (LPA), another serum-borne lysophospholipid that has been shown to be a potent chemoattractant for certain glioblastoma cell lines, including LN229 cells (Fig. 2A; ref. 15). LPA, serum, and EGF also stimulated in vitro invasion of LN229 cells (Fig. 2B), determined by their ability to invade the basement membrane matrix Matrigel, which was also greatly attenuated by SK1-I (Fig. 2B).

**SK1-I reduces basal and stimulated Akt phosphorylation.** S1P-induced glioblastoma cell proliferation is greatly suppressed by inhibition of extracellular signal-regulated kinase (ERK)1/2 and phosphoinositide 3-kinase (PI3K)/Akt pathways (4). Thus, it was of interest to examine the effects of SK1-I on these signaling pathways. We used phospho-specific antibodies to examine phosphorylation of Akt at Thr308 and Ser473 at the COOH terminus, which are required for full activation (18). Consistent with the expression of wild-type PTEN, LN229 cells have low basal Akt phosphorylation, which was rapidly increased by serum, LPA, and EGF, to a lesser extent (Fig. 2C). SK1-I reduced Akt activation induced by all three stimuli. Treatment with SK1-I for only 20 minutes markedly suppressed phosphorylation of Akt at both Thr308 and Ser473 (Fig. 2C). SK1-I also reduced activation of Akt.

![Figure 2](image_url)

**Figure 2.** SK1-I attenuates migration and invasion of glioblastoma cells. **A** and **B**, LN229 cells pretreated with vehicle (open bars) or 10 μmol/L SK1-I (filled bars) were allowed to migrate for 6 h through fibronectin-coated filters (**A**) or invade through Matrigel-coated filters (**B**) toward vehicle (none), LPA (1 μmol/L), serum (5%), or EGF (25 nmol/L), as indicated. Columns, mean number of migrating cells per field; bars, SD; *, P < 0.01. **C**, inhibition of SphK1 by SK1-I inhibits Akt phosphorylation. Serum-starved LN229 cells were pretreated with vehicle or SK1-I (10 μmol/L) for 10 min before stimulation with vehicle, LPA, 5% serum, or EGF for 10, 30, and 120 min, as indicated. Cells were lysed and equal amounts of proteins were analyzed by Western blotting with the indicated antibodies. **D**, S1P reverses SK1-I inhibitory effects on Akt phosphorylation. Serum-starved LN229 cells were pretreated with vehicle or SK1-I (10 μmol/L) for 10 min before stimulation with vehicle, or EGF in the absence or presence of S1P as indicated. Cells were lysed and equal amounts of proteins were analyzed by Western blotting with the indicated antibodies.
p70S6K (Thr389), a downstream target of Akt. In sharp contrast, although serum, LPA, and EGF stimulated ERK1/2 in these short-term assays, SK1-I did not significantly affect stimulated ERK1/2 phosphorylation at Thr202/Tyr204 (Fig. 2C). Moreover, although Akt is active in U373 cells because, such as many human gliomas, they express a nonfunctional mutant form of PTEN that does not inhibit the PI3K/Akt pathway (18), SK1-I reduced their basal Akt phosphorylation at Thr308 and Ser473 (Supplementary Fig. S2B). A significant inhibitory effect was observed within 20 minutes (Supplementary Fig. S2B), which lasted for at least 24 hours (data not shown). As expected, serum and EGF enhanced phosphorylation of Akt, whereas SK1-I reduced it (Supplementary Fig. S2B). The inhibitory effect of SK1-I on Akt phosphorylation was not due to its degradation as there were no significant reductions in total Akt levels after treatment with SK1-I. However, SK1-I did not reduce EGFR- and serum-induced ERK1/2 activation in both U373 (Supplementary Fig. S2B) and LN229 cells (Fig. 2C).

To substantiate that the effects of SK1-I were due to its ability to inhibit SphK1, SIP add-back experiments were carried out. Inhibition of EGF-induced Akt phosphorylation by SK1-I was reversed by addition of SIP (Fig. 2D). EGF has been shown to activate PI3K/Akt by phosphorylating growth factor receptor–bound protein 2–associated binder 1 (19). However, SK1-I did not affect EGF-induced tyrosine phosphorylation of EGF receptor (EGFR) or growth factor receptor–bound protein 2–associated binder 1 (Gab1; Fig. 2D), indicating that SK1-I did not directly interfere with EGFR activation. Thus, the SphK1 inhibitor SK1-I specifically inhibits phosphorylation and activation of Akt in GBM cells in an S1P-dependent manner, consistent with the reduction in levels of S1P by SK1-I (Fig. 3A).

Because down-regulation of SphK1 not only decreases S1P, it also increases ceramide levels (20–23), it was of interest to examine the effects of inhibition of SphK1 with SK1-I on these sphingolipid metabolites that have been reported to have opposing effects on cell growth and apoptosis (24, 25). There was a significant reduction in S1P levels within 20 minutes after addition of SK1-I (Fig. 3A), which correlated with the rapid inhibition of Akt phosphorylation. Furthermore, within 1 hour after addition of SK1-I, S1P levels were dramatically decreased by 70% that was accompanied by an increase in sphingosine levels without major changes in ceramide levels (Fig. 3A). However, after 24 hours of treatment with SK1-I, ceramide levels increased markedly,
particularly proapoptotic C16-ceramide. Unlike safingol (L-threo-dihydrosphingosine; ref. 26), a pan SphK inhibitor, only <1% of SK1-I was converted to the tri-N-methyl metabolite after 24 hours (Fig. 3A) and no other metabolites were detected. Moreover, in contrast to its structural analogue, the immunosuppressant drug FTY720, SK1-I is not readily phosphorylated, ruling out potential actions through S1P receptors.

**Inhibition of c-Jun NH2-terminal kinase attenuates SK1-I–induced cell death.** In agreement with many previous studies showing that down-regulation of SphK1 and ceramide elevation are associated with increased apoptosis (reviewed in refs. 25, 27, 28), treatment with SK1-I induced apoptosis of LN229 cells as shown by increased cleavage of poly ADP ribose polymerase (Supplementary Fig. S3A), a substrate for caspase-mediated proteolysis during apoptosis, increased fragmented and condensed nuclei (Supplementary Fig. S3B), and increased DNA strand breaks detected by terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) staining (Supplementary Fig. S3C). Moreover, SK1-I markedly suppressed long-term survival of LN229 cells in clonogenic assays (Supplementary Fig. S3D).

Sphingolipid metabolites, S1P versus sphingosine and ceramide, usually have opposing effects on Akt and the stress-related c-Jun NH2-terminal kinase (JNK) pathways (24, 25). Concomitant with the inactivation of the cytoprotective Akt pathway, exposure of LN229 cells to SK1-I was accompanied by delayed activation of JNK (Fig. 3B), without affecting p38 mitogen-activated protein kinase (data not shown). Increased phosphorylation of JNK after addition of SK1-I was accompanied by enhanced phosphorylation of its substrates, the transcription factors c-Jun (Ser63/73) and ATF-2 (Thr71; Fig. 3B).

The output of ERK1/2 and Akt signaling versus JNK signaling represents a key homeostatic mechanism that in many cells regulates the balance between cell survival and cell death processes (29). Thus, we next examined the effects of a variety of agents that perturb these signaling pathways on SK1-I–mediated lethality. Inhibition of MAP/ERK kinase 1/2, PI3K, and p38 by U0126,
LY294002, and SB202190, respectively, enhanced SK1-I lethality, whereas inhibition of JNK by SP600125 markedly attenuated the effects of SK1-I in both U373 and LN229 cells (data not shown; Fig. 3C). As expected, SP600125 efficiently blocked JNK activation, as shown by inhibition of c-Jun and ATF-2 phosphorylation (Fig. 3B). Even at 1 μmol/L, a concentration believed to specifically inhibit JNK without having nonspecific effects on other kinases, SP600125 markedly reversed SK1-I–induced lethality (Fig. 3C). We further examined the importance of the JNK pathway using a specific JNK peptide inhibitor. This peptide also significantly reversed the cytotoxic effects of SK1-I (Fig. 3D), whereas the control peptide was ineffective. Similarly, expression of dominant-negative MEK1 also enhanced SK1-I–induced LN229 cell death, whereas dominant-negative Akt did not (Fig. 3D). Moreover, expression of constitutively activated Akt or MEK1, or expression of Bcl-xL, suppressed cell death induced by SK1-I (Fig. 3D).

**Effect of SK1-I on primary nonestablished glioblastoma.** We expanded our observations with SK1-I to primary nonestablished human GBM6 glioblastoma cells, which have been shown to produce invasive, diffuse tumors in the brains of mice (14, 30). GBM6 express mutant p53, wild-type PTEN, and EGFRvIII, a constitutively activated mutant form of EGFR (14, 31). Similar to LN229 and U373 cells, growth of GBM6 cells was greatly reduced by SK1-I (Fig. 4A). In the absence of serum, there was a dose-dependent effect of SK1-I and significant growth inhibition was observed at a concentration as low as 1 μmol/L (Fig. 4A). Moreover, as with the glioblastoma cell lines, 10 μmol/L SK1-I markedly reduced growth of GBM6 in the presence of serum (Fig. 4B). SK1-I also suppressed serum- and EGF-induced invasion of GBM6 (Fig. 4C). Similar to the effects on the established glioblastoma cell lines, SK1-I reduced basal as well as serum- and EGF-stimulated phosphorylation of Akt, without affecting pERK1/2 (Fig. 4D).

**SK1-I reduces tumor growth in mice.** Encouraged by our findings, we investigated the effect of SK1-I on subcutaneous tumor growth of LN229 cells, which are fairly invasive and grow phenotypically similar to invasive gliomas in situ (32). Tumors appeared as palpable masses about 1 week after s.c. injection of one million cells in the flank of a mouse (Fig. 5A). Five days later, when the tumor size could be reliably measured (3–4 mm in diameter), animals were randomized and SK1-I was injected i.p. every other day at a dose of 10 mg/kg. Tumors in control animals...
showed significant increases in volume as early as day 27, and growth accelerated thereafter. Statistical analysis (single factor ANOVA) revealed significantly smaller tumors in the SK1-I treatment group (Fig. 5A). After 43 days, animals had to be sacrificed due to the tumor burden in control mice. Tumors were excised, weighed, and histologically examined. In addition to the tumor volume and size (Fig. 5A and B), SK1-I treatment reduced tumor weight by almost 4-fold (Fig. 5C) and decreased vascularization in tumors, as shown by H&E staining (Fig. 5D). Similar reductions in blood vessel density were observed by staining with antibodies to the mouse-specific endothelial cell marker CD31 (Fig. 5D). In agreement, immunohistochemistry for vascular endothelial growth factor (VEGF) also revealed elevated expression of this angiogenic factor in vehicle-treated tumors that was greatly reduced in SK1-I–treated mice (Fig. 5D). The disruption of tumor cytoarchitecture by SK1-I was accompanied by increased TUNEL-positive apoptotic tumor cells (Fig. 5D). In agreement with attenuation of Akt phosphorylation in GBM cells by SK1-I, immunostaining for phosphorylated Akt in tumors was markedly decreased by treatment with SK1-I (Fig. 5D).

SK1-I enhances survival of mice with LN229 orthotopic tumors. It was of interest to examine whether SK1-I was effective in a more clinically relevant orthotopic model of intracranially implanted LN229 cells. On the basis of trial growth rate analyses, i.p. treatment with SK1-I was initiated at day 20 after intracranial implantation of green fluorescent protein (GFP)–labeled LN229 cells when the tumors would be established and the mice would be expected to be asymptomatic. Animals in the vehicle-treated group began to show symptoms of tumor burden at day 40 and were euthanized on reaching a moribund state between day 43 and 49 (Fig. 6A). None of the SK1-I–treated mice showed any symptoms at this point and SK1-I administration was then halted (Fig. 6A). At day 48, T2W magnetic resonance imaging revealed the presence of a large tumor in the right hemisphere of vehicle-treated mice (Fig. 6B), whereas no tumors were evident in SK1-I–treated mice (Fig. 6B). Gadolinium enhancement revealed a small tumor in the brain of this SK1-I–treated mouse at the site of the injection (Fig. 6C). Moreover, visualization of GFP-labeled LN229 cells in intracranial tumor sections showed significantly fewer invading cells and noticeable areas of necrosis in the middle of the tumors from SK1-I–treated animals compared with vehicle-treated animals (Fig. 6D). Kaplan-Meier survival analysis of intracranial glioblastoma xenografts showed significant survival benefit from SK1-I administration compared with vehicle control animals (Fig. 6A), indicating that SK1-I was remarkably efficacious in the brain even when administered i.p.

Discussion
Currently available therapies only minimally improve the prognosis of GBM patients, and new therapeutic targets are desperately needed. Accumulating evidence suggests that SphK1 is an attractive new target. SphK1 message and protein levels are up-regulated in GBM (2) and in astrocytoma tissues compared with adjacent normal brain (3). Patients whose tumors were among the highest one-third with regard to SphK1 expression survived a median of 102 days, whereas those within the lower two-thirds survived a median of 357 days (2). High expression of SphK1 was shown to be a predictor of poor prognosis for astrocytoma patients (3).

Here, we show that targeting SphK1 with SK1-I suppressed proliferation of several human glioblastoma cell lines, including U373, LN229, U87, and U118 cells as well as nonestablished GBM6 cells. SK1-I also potently induced apoptosis and inhibited invasion of these cells. Similar to the effects of SK1-I, down-regulation of
SphK1 expression has been shown to reduce glioblastoma cell growth, survival, migration, and invasion (2). SK-I was effective in GBM that are mutant for PTEN or p53 or have a constitutively activated form of EGFR. This is particularly important because >80% of GBMs show strong Akt activation, many due to lost or mutated PTEN. Activation of EGFR is also a critical pathogenetic event, with amplifications, mutations, or rearrangements commonly observed (33). SK-I also showed significant antitumor activity in vivo, inducing GBM tumor apoptosis and reducing tumor vascularization.

We have begun to unravel the mechanisms by which inhibition of SphK1 by SK-I so profoundly reduces proliferation and survival of GBM in vitro and inhibits tumor growth in vivo. SK-I rapidly suppresses phosphorylation of Akt and its targets p70S6K and GSK3β, and thus interferes with signaling through the Akt pathway, which is frequently activated in gliomagenesis (33). This inhibition by SK-I is not due to a direct effect on Akt, as it did not inhibit Akt activity in an in vitro kinase assay (11). It is also well accepted that S1P produced by activation of SphK1 is released from cells and stimulates its receptors that are linked to activation of Akt. Indeed, the reduction of S1P levels by SK-I is rapid and could contribute to decreased phosphorylation of Akt. The effects of SK-I may not be mediated solely by reduction of “inside-out signaling” by S1P but also by reduction of intracellular S1P. Our results are consistent with previous reports showing that SphK1 and intracellular S1P are critical for Akt activation and cell proliferation independently of S1P receptors (6, 34). Moreover, in 1321N1 glioblastoma cells, DNA synthesis and cyclin D expression were increased in a SphK1- and Akt-dependent manner independently of S1P receptors (6). In agreement, overexpression of SphK1 promotes cell survival and growth even in cells devoid of functional S1P receptors (34). Similarly, overexpression of SphK1 is a S1P receptor–independent oncogenic event in progression of erythroleukemia that involves activation of Akt (35). In agreement with previous results in leukemia cells (11), SK-I not only inhibited S1P production in glioma cells, it also increased levels of its proapoptotic precursor ceramide that has been shown to cause growth inhibition and apoptosis by inhibiting Akt (25). Thus, biphasic inhibition of Akt is likely due to a rapid decrease in intracellular S1P and later sustained increases in ceramide. Furthermore, a recent study in glioma cells showed that inhibition of the Akt pathway strongly up-regulated ceramide levels by inhibiting conversion of ceramide to complex sphingolipids due to reduction of endoplasmic reticulum to Golgi trafficking of ceramide (36). Because ceramide in turn further inhibits Akt, this positive feedback loop amplifies the apoptotic effect of SK-I. Activation of JNK may also be due to inhibition of Akt following SK-I treatment as several studies raised the intriguing possibility that the ability of Akt to inhibit JNK signaling is due to phosphorylation of specific upstream targets in this pathway (37, 38).

Down-regulation of SphK1, similar to SK-I, causes a marked elevation in levels of ceramide (20–23). Consistent with the higher expression of SphK1 in GBM, ceramide levels are lower in human gliomas compared with surrounding brain tissue, and are inversely related to tumour progression and short patient survival (39). Thus, actions of SphK1 might be related to its role in regulation of ceramide levels.

The existence of redundant survival pathways suggests that targeting a single dysregulated pathway may not be sufficient to eliminate tumors. Indeed, it has been suggested that effective GBM therapy may require combinations of inhibitors targeting multiple signaling pathways (40). Our finding that inhibiting SphK1 with SK-I further enhanced glioblastoma cell lethality induced by inhibitors of other important signaling pathways that are frequently deregulated in GBM may have implications for the design of protocols combining SphK1 inhibitors together with conventional anticancer agents or experimental therapeutics.
