Abstract
Accumulating evidence indicates the crucial contribution of chronic inflammation to various types of carcinogenesis, including colon carcinoma associated with ulcerative colitis and asbestos-induced malignant mesothelioma. Ulcerative colitis–associated colon carcinogenesis can be recapitulated in mice by azoxymethane administration followed by repetitive dextran sulfate sodium ingestion. In the course of this carcinogenesis process, the expression of a macrophage-tropic chemokine, CCL2, was enhanced together with intracolonic massive infiltration of macrophages, which were a major source of cyclooxygenase (COX)-2, a major mediator of colon carcinogenesis. Mice deficient in CCL2-specific receptor, CCR2, exhibited less macrophage infiltration and lower tumor numbers with attenuated COX-2 expression. Moreover, CCL2 antagonists decreased intracolonic macrophage infiltration and COX-2 expression, attenuated neovascularization, and eventually reduced the numbers and size of colon tumors, even when given after multiple colon tumors have developed. These observations identify CCL2 as a crucial mediator of the initiation and progression of chronic colitis–associated colon carcinogenesis and suggest that targeting CCL2 may be useful in treating colon cancers, particularly those associated with chronic inflammation. [Cancer Res 2009;69(19):7884–92]

Introduction
Ulcerative colitis (UC) is a major form of inflammatory bowel disease (IBD), an immune-mediated chronic intestinal condition (1). The major symptom of UC is bloody mucoid diarrhea and its clinical course is characterized by repetitive relapses and remissions. Pathologic features of UC include prominent leukocyte infiltration in the colonic mucosa and uncontrolled and prolonged inflammatory reactions (1). These conditions frequently cause epithelial dysplasia and DNA damage with microsatellite instability, and eventually can progress to cancer (2). Indeed, involvement of entire colon for longer than 10 years predisposes UC patients to colon cancer (2), indicating the essential contribution of chronic inflammation to colon carcinogenesis. Thus, to develop measures to prevent cancer development in UC patients, it is necessary to gain an understanding of the pathogenesis of UC at molecular and cellular levels. Moreover, evidence is accumulating that chronic inflammatory conditions also can cause cancer in other organs as observed on asbestosis and silicosis (3). Thus, elucidation of colon carcinogenesis in UC will also shed a novel light on chronic inflammation-associated carcinogenesis in general.

Oral administration of dextran sulfate sodium (DSS) to rodents is widely used to recapitulate human UC, because it can induce pathologic changes similar to that observed in UC patients (4). Moreover, repeated oral DSS ingestion can cause colon carcinoma (5) and this carcinogenesis process is promoted by a prior administration of azoxymethane (AOM), which causes O6-methylguanine formation (6). Activation of NF-κB pathway contributes to this colon carcinogenesis by preventing colon epithelial cell apoptosis and promoting growth factor production by inflammatory cells (7). The crucial involvement of NF-κB activation in colon carcinogenesis prompted us to investigate the roles of the tumor necrosis factor (TNF)-α/TNF receptor axis, because TNF-α is abundantly expressed in colon of patients with IBD (8), and is one of major target molecules of NF-κB and a major activator of NF-κB (9). We showed that combined treatment with AOM and DSS induced the intracolonic expression of TNF-α, which in turn regulates the trafficking of macrophages and granulocytes, major sources of cyclooxygenase (COX)-2, thereby resulting in the development and progression of colon cancer (10).

TNF-α lacks direct chemotactic activities for macrophages and granulocytes, but can induce the expression of various chemokines in several cell types present in colon tissues such as epithelial cells, fibroblasts, endothelial cells, and leukocytes (9). Thus, it is likely that enhanced TNF-α expression in colon tissues can induce the expression of chemokines active on macrophages and granulocytes. Indeed, the mucosa of patients with IBD exhibited enhanced mRNA and protein expression of MCP-1/CCL2 (11–13), a C-C chemokine with potent chemotactic and activating activities for monocytes/macrophages (14). We previously consistently observed that combined treatment of AOM and DSS enhanced CCL2 mRNA expression in colon tissues and that blocking the TNF-α/TNF receptor axis reduced colorectal carcinogenesis, intracolonic macrophage infiltration, and CCL2 mRNA expression (10). These observations prompted us to
investigate the roles of the interaction between CCL2 and its specific receptor, CCR2, in colon carcinogenesis induced by the combined treatment with AOM and DSS. By using CCR2-deficient mice and CCL2 blocking agents, we here document that CCL2 interactions with CCR2 have vital roles in the initiation and progression of colitis-associated colon carcinogenesis.

Materials and Methods

Reagents and antibodies. AOM and DSS (MW 36,000–50,000) were purchased from Sigma-Aldrich, Inc. and MP Biomedicals, Inc., respectively. A specific CCR2 antagonist, propargamanium, was kindly provided by Sanwa Chemical Co. Human CCL2 NH2-terminal deleted form 7ND-expressing vector was prepared by cloning human CCL2 NH2-terminal-deleted cDNA with an epitope FLAG tag in the carboxyl terminal portion to the pcDNA3 expression vector as described previously (15). Rat monoclonal anti-F4/80 antibody was obtained from Serotec. Goat polyclonal anti-β-catenin and mouse monoclonal anti-cytokeratin 20 antibodies were obtained from Santa Cruz Biotechnology and Abcam, respectively. Rabbit polyclonal anti-CCL2 and anti-CCR2 antibodies were obtained from Biovet. Goat polyclonal anti—COX-2 antibody was obtained from Santa Cruz Biotechnology and Abcam, respectively. Rabbit polyclonal anti-F4/80 antibody was obtained from Serotec. Goat polyclonal anti-CCR2 and anti-CCL2 antibodies were prepared by immunizing rabbits with mouse tissue culture CCL2 and CCR2 peptide as previously described (16).

Animal experiments. Pathogen-free 6- to 12- week-old female wild-type BALB/c mice (WT) and CCR2-deficient mice, on a BALB/c genetic background, were housed under specific pathogen-free conditions with free access to food and water during the course of experiments. Mice were injected i.p. with 12 mg/kg body weight of AOM dissolved in physiologic saline. Five days later, 2% DSS was given in the drinking water over 5 d, followed by 16 d of regular water. This cycle was repeated a total of thrice. Body weights were measured every week and the animals were sacrificed at the indicated time intervals for macroscopic inspection, histologic analysis, and total RNA extraction. In some experiments, 7ND-expressing or pcDNA3 vector was injected into the femoral muscle of WT mice at day 56. Immediately after the injection, a pair of electrode pads was inserted onto the muscle to encompass the injected site, and electrical pulses were delivered six times (100V, 50-ms pulse) with an electrical pulse generator (ECMB80, BTX). At 11 d after the transfection, reverse transcription-PCR detected 7ND gene expression selectively in muscle of mice receiving 7ND-expressing vector (Supplementary Fig. S1A). Moreover, immunohistochemical analysis detected 7ND protein in the muscle of WT mice receiving 7ND-expressing vector, but not those receiving pcDNA3 vector (Supplementary Fig. S1B). In another series of experiments, WT mice were given propargamanium at a dose of 8 mg/kg body weight, mixed with the food, every day from day 56 to day 60. All animal experiments were performed in compliance with the Guideline for the Care and Use of Laboratory Animals of Kanazawa University.

Bone marrow chimeric mice generation. Cell suspensions from male WT or CCR2-deficient bone marrow were prepared from femurs and tibias, filtered, and counted. Female WT or CCR2-deficient mice received a single i.v. injection of 1 × 107 bone marrow cells, after being irradiated with 4.25 Gy X-rays followed by 4.25 Gy X-rays (MPR-1520R, Hitachi) 4 h later. The following groups of chimeric mice were generated: WT to WT, WT to CCR2 deficient, CCR2 deficient to WT, and CCR2 deficient to CCR2 deficient mice. To verify successful reconstitution of bone marrow in recipient mice, genomic DNA was extracted from peripheral blood. Quantitative PCR was performed to detect Sry gene present in the Y chromosome (forward, 5'-TGGGACTCTCATCACTTCTG-3'; reverse, 5'-CTCTGTATTTTGCATG-3') and GAPDH gene as an internal control with the help of Fast SYBR Green Master mix (QIAGEN) as described previously (17). We calculated the chimeric rates on the assumption that the ratio of Sry to GAPDH gene was 100% in male mice. We confirmed that the rates of WT to CCR2-deficient and CCR2-deficient to WT mice were 97.6 ± 2.4% and 84.2 ± 5.0%. After bone marrow reconstitution was confirmed, mice were given sequentially with AOM and DSS as described above.

Histopathological and immunohistochemical analyses of mouse colon tissues. Resected mouse colon tissues were fixed in 10% formalin neutral buffer solution (Wako) for paraffin embedding or were immediately frozen in Tissue-Tek ornhine carbamyl transferase compound (Sakura Fine Chemical Co.) and stored at −80°C. Paraffin-embedded sections were cut at 5 μm and stained with H&E solution. Paraffin-embedded sections were additionally deparaffinized for immunohistochemical detection of β-catenin, COX-2, CCL2, CCR2, Ly-6G–, Cytokeratin 20–, and FLAG-positive cells. Frozen sections were used for immunohistochemical detection of mouse CD31-positive cells. Endogenous peroxidase activity was blocked using 3% H2O2 for 5 min, followed by incubation with Non-Specific Staining Blocking reagent (DakoCytomation) for 10 min. The sections were incubated with the optimal dilutions of anti-CCR2, anti-CCL2, anti-F4/80, anti-CD3, anti-β-catenin, anti-COX-2, anti-CD31, anti-cytokeratin 20, or anti-FLAG antibodies overnight at 4°C. β-Catenin– and CCR2-positive cells were detected with horseradish peroxidase–labeled anti-rabbit polymer (EnVision+ System, DakoCytomation), whereas F4/80-positive cells were detected using Catalyzed Signal Amplification System (DakoCytomation). Immune complexes were visualized with Peroxidase Substrate 3,3′-diaminobenzidine (DAB) kit (Vector Laboratories, Inc.), CCL2–, COX-2–, and CD31-positive cells were detected by the incubation with anti-rabbit, anti-goat, or anti-rat biotinylated IgG (DakoCytomation; dilution, 1:200). Detection of cytokeratin 20 and FLAG tag was performed with Vector M.O.M. Immunodetection kit (Vector Laboratories, Inc.) according to the manufacturer’s instructions. The resultant immune complexes were visualized by ABC Elite kit (Vector Laboratories, Inc.) and Peroxidase Substrate DAB kit (Vector Laboratories, Inc.) according to the manufacturer’s instructions. Finally, the slides were counterstained with hematoxylin, dehydrated, and coverslipped. Positive cells were enumerated on five randomly chosen visual fields at ×400 magnification. The pixel numbers of CD31-positive areas were measured on five randomly chosen visual fields at ×200 magnification with the aid of Adobe Photoshop software.

A double-color immunofluorescence analysis. Colon tissues were processed to a double-color immunofluorescence analysis using the combination of anti-CCR2 and anti-COX–2 antibodies. Alexa Fluor 488 donkey anti-rabbit and Alexa Fluor 568 donkey anti-goat antibodies were used as secondary antibodies. Immunofluorescence was visualized on a Carl Zeiss Laser Scanning Microscope 510.

RT-PCR analysis. Total RNA was extracted from colon or muscle tissues with RNAasy Mini kit (QIAGEN) and 2.5 μg of RNA was reverse transcribed using ReverTAce and random primers as described previously (10). Thereafter, 2 μL of resultant cDNA was used to amplify 7ND and GAPDH gene using Taq DNA polymerase and 10 μmol/L of specific sets of primers with the predetermined optimal cycle consisting of 94°C for 30 s, 55°C for 1 min, and 72°C for 1 min (Supplementary Table S1) as described previously. The PCR products were fractionated on 1.5% agarose gel and visualized by ethidium bromide staining. Real-time PCR was performed on Applied Biosystems StepOne Real-Time PCR System using the comparative Ct quantitation method. TaqMan Gene Expression Assays (Applied Biosystems), containing specific primers and TaqMan MGB probe (FAM dye-labeled), TaqMan Fast Universal PCR Master Mix were used with 10 ng of cDNA to detect and quantify the expression levels of CCL2 and COX-2 in mouse colon tissues. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was amplified as internal control. Ct values of GAPDH were subtracted from Ct values of the target genes (Δ Ct), Δ Ct values of treated mice were compared with Δ Ct values of untreated animals. Reactions were done at 95°C, 20 s, then 95°C, 60 s, 60°C, 20 s, 40 cycles.

DNA sequencing and mutation analysis of β-catenin gene. Genomic DNA was extracted from tumor tissues obtained from WT mice receiving either 7ND-expressing or pcDNA3 vector by using NucleoSpin Tissue Kit (Macherey-Nagel, Inc.) according to the manufacturer’s instructions. Exon 3 of the β-catenin gene, containing the consensus sequence for glycogen synthase kinase-3β phosphorylation, was amplified by PCR, using specific primers (forward, 5′-GCTGACCTGATGATGATGAG-3′; reverse, 5′-GCTACTTGTCTTGCTGGTGA-3′) and the following thermal cycling parameters: 35 cycles of 94°C, 5 min; followed by 94°C, 45 s, 55°C, 1 min, 72°C, 1 min; followed by 72°C, 5 min. PCR products were subcloned into...
pSTBlue-1 vector (AccepTor vector, Novagen) and sequenced using BigDye Terminator Ver. 3.1 Cycle Sequencing kit (Applied Biosystems) on an ABI PRISM 3100-Avant Genetic Analyzer (Applied Biosystems).

**Statistical analysis.** The mean ± SD were calculated for all parameters determined. Statistical significance was evaluated using one-wayANOVA, and P values lower than 0.05 were considered statistically significant.

**Results.**

Enhanced CCL2 expression in the colon during the course of colon carcinogenesis. Consistent with our previous observations (10), a single i.p. injection of the carcinogen AOM, followed by three rounds of 2% DSS intake, induced the development of multiple tumors from the middle to distal colon of WT mice (Supplementary Fig. S2; Fig. 1A). Because we previously observed a massive macrophage infiltration during the whole course of this colon carcinogenesis process, we investigated the expression of a macrophage-tropic chemokine MCP-1/CCL2 and its single specific receptor, CCR2. CCL2 mRNA expression level was negligible in untreated WT mice and immediately after AOM treatment, but subsequent to DSS administration, CCL2 mRNA expression was augmented with a fluctuation (Fig. 1B). Similarly, CCR2 mRNA level was enhanced in WT mice after DSS intake (Fig. 1C) but CCR2 mRNA could not be detected in CCR2-deficient mice under the present experimental conditions (data not shown). CCL2 protein was detected in mononuclear cells, particularly macrophages, infiltrating the lamina propria and submucosal regions, and also in endothelial cells at the earlier phase and colon carcinoma cells at the later phase (Fig. 1D, top). Immunohistochemical analysis showed that CCR2 was expressed by mononuclear cells infiltrating in the lamina propria and submucosal regions of the colon, and by some colon carcinoma cells during the course of colon carcinogenesis (Fig. 1D, bottom).

Reduction in AOM/DSS-induced inflammatory reaction and subsequent tumor formation in the absence of CCR2. A massive infiltration of CCR2-positive cells prompted us to investigate the roles of the CCL2-CCR2 interactions in this colon carcinogenesis. There were no apparent differences in macroscopic and microscopic appearance of the colon of untreated WT and CCR2-deficient mice (Fig. 2A). When both strains were treated with AOM and DSS, WT mice exhibited marked bodyweight loss and bloody diarrhea, whereas CCR2-deficient mice showed a minimal body weight loss and diarrhea (data not shown). In WT mice, multiple tumors extended from most of the middle to distal colon by day 56, whereas the numbers and sizes of tumors were remarkably reduced in CCR2-deficient mice (Fig. 2B). Immunohistochemical analysis showed that the number of CCL2-positive cells was markedly reduced in CCR2-deficient mice compared with WT mice, consistent with the reduction in colon tumor formation (Fig. 2C). These results suggest that CCR2 plays an important role in colon carcinogenesis mediated by CCL2.

in the colons of CCR2-deficient mice even at day 56 (Supplementary Fig. S2; Fig. 1A). Microscopic analysis consistently showed that WT mice developed severe inflammation with massive infiltration of leukocytes into the mucosa, submucosal edema, and loss of entire crypts and surface epithelium, particularly in the middle to distal colon at day 7 (Fig. 2A). At day 14, inflammatory cell infiltration persisted, accompanied with dysplastic glands with hyperchromatic nuclei, decreased mucin production, and dystrophic goblet cells. Moreover, immunohistochemical analysis showed that inflammatory cells consisted of F4/80-positive macrophages (Fig. 2C). AOM treatment most frequently causes mutations of β-catenin and eventually constitutive activation of the Wnt signaling pathway (18). These molecular changes are mirrored by nuclear accumulation of β-catenin in tumor cells. Indeed, at days 28 to 35, adenocarcinomatous lesions exhibited nuclear β-catenin accumulation together with macrophage and granulocyte infiltration, and their sizes and numbers increased progressively, thereafter (Fig. 2A and B). On the contrary, CCR2-deficient mice displayed only mild inflammatory changes in the colon during the course of DSS administration as evidenced by attenuated infiltration of macrophages (Fig. 2C) and eventually developed only a small number of adenocarcinomatous lesions with less nuclear β-catenin accumulation (Fig. 2A and B). These observations identified the CCL2-CCR2 interactions as crucial for the development of chronic inflammation-associated colon carcinoma.

**Contribution of CCR2-expressing bone marrow–derived cells to colon carcinogenesis.** CCR2 is expressed by nonbone marrow as well as bone marrow–derived cells (19, 20), and we observed CCR2 expression on some cancer cells. Hence, we compared the contribution of CCR2-expressing nonbone

marrow– and bone marrow–derived cells to this colon carcinogenesis by using bone marrow chimeric mice prepared from WT and CCR2-deficient mice. Upon combined treatment with AOM and DSS, CCR2-deficient and WT mice transplanted with WT mouse–derived bone marrow cells developed tumors with a similar incidence, but at a much higher level than either WT or CCR2-deficient mice transplanted with CCR2-deficient mouse–derived bone marrow (Fig. 3). These observations would indicate that CCR2-expressing bone marrow–derived cells, but not nonbone marrow–derived cells were mainly responsible for tumor development in this model.

**Reduction in AOM/DSS-induced expression of COX-2 in CCR2-deficient mice.** COX-2 mRNA expression and COX-2–expressing cell number were increased in WT mice following 7 days after the initiation of DSS treatment (Fig. 4A–C) as we previously observed (10). We did not observe any positive staining when we used an isotype IgG instead of anti–COX-2 antibody (data not shown), confirming the specificity of this antibody. In line with our previous observation that COX-2 was expressed by F4/80-positive macrophages, double-color immunofluorescence analysis revealed that the cells that expressed CCR2 also expressed COX-2 (Fig. 4D). AOM/DSS-induced increases in COX-2 mRNA expression and COX-2–positive cell numbers were decreased in the absence of CCR2 (Fig. 4A–C). Collectively, AOM/DSS failed to increase the expression of COX-2, an enzyme that is crucially involved in colon carcinoma development, in CCR2-deficient mice.

**Reduction of tumor formation by CCR2 antagonist administration.** To further delineate the role of the CCL2-CCR2 interactions in the progression phase of this colon carcinogenesis model, we administered two distinct types of CCR2 antagonists, 7ND-expressing vector and propagermanium, after three cycles of DSS intake, when multiple colon tumors have developed. When mice were treated with 7ND-expressing vector, the numbers and sizes of macroscopic tumors were markedly reduced (Fig. 5A and B). Histopathologic analysis showed that treatment with 7ND-expressing vector attenuated adenocarcinomatous changes (Fig. 5C). Likewise, propagermanium treatment reduced the numbers and sizes of tumors and attenuated adenocarcinomatous changes (Supplementary Fig. S3A–C). Concomitantly, treatment with 7ND-expressing vector (Fig. 5D) or propagermanium (Supplementary Fig. S3D) decreased the numbers of infiltrating macrophages. 7ND administration reduced intracolonic COX-2 mRNA expression and COX-2–expressing cell numbers (Supplementary Fig. S4A; Fig. 6A). Moreover, 7ND treatment decreased intratumoral CD31-positive vascular areas significantly (Supplementary Fig. S4B; Fig. 6B). Similarly, reductions in COX-2 expression and intratumoral vascular areas were observed with propagermanium treatment (Supplementary Figs. S5 and S6). Furthermore, 7ND treatment decreased nuclear accumulation of β-catenin in the tumor cells (Supplementary Fig. S4C; Fig. 6C) and the numbers of cytokeratin 20–positive cells (Supplementary Fig. S4C; Fig. 6D). Likewise, propagermanium treatment decreased both β-catenin nuclear accumulation in the tumor cells and cytokeratin 20–positive cell numbers (Supplementary Fig. S7). Finally, the incidence of β-catenin mutations was significantly reduced by 7ND treatment (Supplementary Table S2). Collectively, these observations would indicate that CCL2-CCR2 interactions were also crucially involved in the tumor progression phase after multiple tumors developed, by regulating COX-2–expressing macrophage infiltration.

**Discussion**

CCL2 was originally identified as a chemokine, which is chemoattractant for monocytes and macrophages (14). Although most chemokines can bind several distinct receptors with similar affinities, CCL2 uses CCR2 as its single specific receptor (21). Subsequent studies have unraveled the crucial roles of the CCL2-CCR2 interactions in various chronic inflammatory conditions characterized by a macrophage infiltration, such as crescentic glomerulonephritis (22), pulmonary hypertension (23), pulmonary fibrosis (24), atherosclerosis (25), multiple sclerosis (26), and rheumatoid arthritis (27). Moreover, CCL2 mRNA and protein expression was augmented in the mucosa of patients with IBD (11–13). In a recent study, administration of the antioxidant N-acetyl-l-cysteine to UC patients had beneficial effects together with down-regulation of CCL2 expression levels (28). DSS administration augmented CCL2 mRNA expression with a fluctuation in the course of colon carcinogenesis. This may mirror the observations that CCL2 protein was detected in macrophages and that the macrophage numbers fluctuated in the course of colon carcinogenesis process. Moreover, genetic deletion of CCR2 protected mice from DSS-induced acute inflammatory changes as previously reported (29). Thus, the CCL2-CCR2 interactions can initiate colon carcinogenesis by inducing inflammation in the colon.

In addition to hematopoietic cells such as macrophages, CCR2 is also expressed by nonhematopoietic cells such as endothelial cells (30), fibroblasts (31), and mesenchymal stem cells (32). In line with the previous observation that CCR2 is expressed by prostate cancer cells (33), we detected CCR2 expression on some cancer cells as well as by infiltrating mononuclear cells in this model. However, the analysis of bone marrow chimeric mice revealed that bone marrow–derived CCR2-expressing but not nonbone marrow–derived cells are indispensable for this colon carcinogenesis, although contribution of bone marrow–derived endothelial progenitor cells (34) and/or fibrocytes (35) cannot be completely excluded.
Andreas and colleagues (29) claimed that upon DSS treatment, CCR2- or CCR5-deficient mice exhibited reduced acute colitis, but with similar level of macrophage infiltration as WT mice. On the contrary, combined blockade of CCR2, CCR5, and CXCR3 protected mice from DSS-induced colitis along with a reduction in intra-colonic infiltration of CD11b-positive macrophages (36). We also observed that macrophage infiltration was markedly reduced in CCR2-deficient mice after DSS treatment, compared with WT mice. Moreover, intracolonic macrophage infiltration was also reduced by two distinct CCL2 antagonists, 7ND-expressing vector and propagermanium. Thus, the CCL2-CCR2 interactions regulate intracolonic infiltration of macrophages under our present conditions.

Solid tumors including colon cancers are infiltrated with leukocytes, which sometimes account for up to 50% of tumor mass, the most represented populations being lymphocytes and macrophages (37). The presence of lymphocytes is considered as evidence of an immunologic antitumor response, whereas the presence of tumor-associated macrophages (TAM) represents a hallmark of cancer-associated inflammation (37). TAM originate from circulating monocytes that are attracted by chemotactic factors produced locally by tumor cells and resident cells. TAM produce IL-10 and transforming growth factor-β to dampen immune response to tumor cells and concomitantly promote tumor growth by producing angiogenic and growth factors. CCL2 was originally identified as a tumor-derived chemotactic factor for macrophages (38). Accumulating evidence indicates that the levels of tumor-derived CCL2 significantly correlate with TAM density and the depth of invasion in cancers of various organs (37). Moreover, experimental studies using xenotransplanted or iso-transplanted tumors revealed the involvement of the CCL2-CCR2 axis in cancer invasion and metastasis (16, 39).

To clarify the roles of the CCL2-CCR2 in the progression phase of this colon carcinogenesis model, we used two different measures to

**Figure 4. COX-2 expression in the colons.** A, quantitative RT-PCR was performed on total RNAs extracted from the colons at the indicated time points as described in Materials and Methods. The levels of COX-2 mRNA were normalized to the levels of GAPDH mRNA. *, P < 0.05; **, P < 0.01 versus untreated mice. B and C, immunohistochemical detection of COX-2–expressing cells. block CCL2 activity; i.m. injection of 7ND expression vector and administration of propagermanium. The biological activity of CCL2 depends on the integrity of its NH2 terminus and 7ND, a mutant protein lacking NH2-terminal amino acids 2 to 8, which can form a heterodimer with WT CCL2 protein (15), to suppress CCL2 activity (40). I.m. transduction of 7ND-expressing vector can result in continuous i.m. 7ND protein expression and its subsequent secretion into the circulation (41), thereby preventing CCL2-mediated tissue injuries such as vascular remodeling (41), atherosclerosis (41), and renal fibrosis after reperfusion injury (42). 7ND could effectively block CCL2 function in vivo and suppress inflammatory and proliferative changes in animal models of cardiovascular diseases (43), as well as in a model of renal fibrosis (44). Another CCR2 inhibitor, propagermanium, targets glycosylphosphatidylinositol-anchored proteins associated closely with CCR2, and selectively inhibits MCP-1/CCR2 signaling (45). Both measures attenuated intracolonic macrophage infiltration and neovascularization, and eventually reduced the numbers and sizes of colon carcinomas. Thus, it is reasonable to speculate that the CCL2 axis is crucially involved in the progression phase of colon carcinogenesis by regulating macrophage infiltration.

TAM can produce various factors to promote tumor growth and angiogenesis. Among them, prostaglandin E2 (PGE2) is presumed to be crucially involved in colon carcinogenesis because it can induce neovascularization (46) and activate a pathway crucial for colon carcinogenesis, the Wnt/β-catenin pathway, through activation of phosphoinositide 3-kinase/Akt-G protein αi,axin signaling axis (47) and inhibition of glycogen synthase kinase-3 (48). COX-2 is an important enzyme in PGE2-generating pathway and its expression is highly inducible in various types of cells including macrophages (49). COX-2 protein was detected in infiltrating F4/80-positive cells (10) and CCR2-expressing cells. Moreover, CCL2 can induce COX-2 expression in human monocytes (50). Thus, CCL2 blocking may reduce the infiltration of COX-2–expressing F4/80-positive cells and depress COX-2 expression by infiltrating macrophages, and eventually inhibit the Wnt signaling pathway and neovascularization, resulting in retardation of cancer progression.

Based on our previous observation that blocking TNF-α reversed colon carcinoma progression even after colon carcinoma was established, we proposed that drugs targeting TNF-α may be useful for the treatment of colon cancers, particularly those arising from chronic inflammation (10). Blocking CCL2 retarded colon cancer progression in this model with similar efficacy as TNF-α blockade, when given after multiple colon tumors were developed. Thus, drugs targeting CCL2 may be effective for the treatment of chronic inflammation-associated colon cancer, similarly to those targeting TNF-α.

Figure 5. The effects of 7ND-expressing vector injection on colon carcinogenesis. A, macroscopic evaluation of the tumors. Colons were removed on day 67 from WT mice, injected with 7ND-expressing or with pcDNA3 vector. Representative results from seven to eight independent animals are shown here. B, the tumor numbers and sizes were determined macroscopically. Bars, the mean of each group. Each symbol represents the tumor numbers of each animal or the average size of the tumors of each animal. **, $P < 0.01$ versus WT mice injected with pcDNA3 vector. C, tumors were processed to H&E staining and representative results from six independent animals are shown. Scale bar, 50 μm. D, F4/80-positive macrophages were enumerated as described in Materials and Methods. Columns, mean (n = 5 animals); bars, SD. *, $P < 0.05$; **, $P < 0.01$ versus WT mice injected with pcDNA3 vector.
TNF-α. Because TNF-α has a wide variety of biological functions (9), TNF-α blocking agents can have serious adverse effects including the induction of bacterial, tuberculosis, and opportunistic infection (51). CCL2 has a limited biological function, and therefore, drugs targeting CCL2 might have less severe adverse effects than those targeting TNF-α.
