Abstract

Constitutive activation of the nuclear factor-κB (NF-κB) transcription factor plays a key role in chronic colonic inflammation and colon tumorigenesis. However, the mechanisms by which the tightly regulated NF-κB pathway becomes constitutively activated during colon pathogenesis remain obscure. Here, we report that PDLIM2, an essential terminator of NF-κB activation, is repressed in various human colorectal cancer cell lines, suggesting one important mechanism for the constitutive activation of NF-κB. Indeed, expression of exogenous PDLIM2 inhibited constitutive NF-κB activation in these colorectal cancer cells. Importantly, the PDLIM2 expression was sufficient to suppress in vitro anchorage-independent growth and in vivo tumor formation of these malignant cells. We have further shown that the PDLIM2 repression involves promoter methylation. Accordingly, treatment of the colorectal tumor cell lines with the DNA methyltransferase inhibitor 5-aza-2′-deoxycytidine restored PDLIM2 expression and resulted in growth arrest. These studies thus provide new mechanistic insights into colon tumorigenesis by identifying a novel tumor suppressor role for PDLIM2. Cancer Res; 70(5) March 1, 2010.

Introduction

Colon cancer is the third most common malignancy and is the second leading cause of cancer death (1). One major predisposition for colon cancer development is chronic colonic inflammation, particularly in patients with inflammatory bowel diseases including Crohn’s disease and ulcerative colitis (2). For example, the cumulative incidence of colitis-associated cancer is up to 20% to 50% in patients with ulcerative colitis, accounting for one sixth of deaths in patients with inflammatory bowel disease (3). Both mouse and human studies suggest that the nuclear factor-κB (NF-κB) transcription factor plays a causative role in chronic colonic inflammation, and subsequently, the pathogeneses of inflammatory bowel disease and colitis-associated cancer. An NF-κB defect in mouse intestinal epithelial cells or myeloid cells leads to a significant decrease in colitis-associated cancer (4), whereas constitutively activated NF-κB is detected in gut macrophages and epithelial cells of biopsy specimens as well as in colorectal cancer but not in adjacent normal tissue from patients with inflammatory bowel disease (5–8). Moreover, inhibition of NF-κB reduces the risk of colitis-associated cancer by 75% to 81% (9, 10).

NF-κB activity is tightly controlled under physiologic conditions (11). In response to different stimuli, NF-κB is rapidly activated but usually transiently (12). One essential mechanism for the quick termination of the NF-κB response involves nuclear degradation of its prototypic member p65 (13), which is predominantly mediated by PDLIM2 (14). PDLIM2 is the most recently discovered PDZ-LIM domain–containing protein. It has been suggested that the COOH-terminal LIM domain of PDLIM2 is required for promoting ubiquitination of nuclear p65, whereas its NH2-terminal PDZ domain is involved in shuttling nuclear p65 along the nuclear framework into discrete intranuclear compartments for proteasome-mediated degradation. Accordingly, PDLIM2 knockout mice are more sensitive to lipopolysaccharide-induced shock due to enhanced NF-κB/p65 activation and augmented production of inflammatory cytokines (14).

Currently, the mechanism of constitutive NF-κB activation during intestinal pathogenesis remains largely unknown. Here, we show that PDLIM2 is epigenetically repressed in various human colorectal cancer cell lines. PDLIM2 re-expression inhibited NF-κB constitutive activation, in vitro anchorage-independent growth, and in vivo tumor formation of these malignant cells. These studies suggest one important mechanism for the constitutive activation of NF-κB in colon tumorigenesis and a novel tumor suppressor role for PDLIM2 in colorectal cancer.

Expression vectors and reagents. pQCXIP-myc-PDLIM2, x-b-TATA luciferase reporter constructs, and PDLIM2 antibody have been previously described (15). The anti-Myc antibody was generated from the 9E10 hybridoma as described (16). Nucleoside analogue 5-aza-2′-deoxycytidine (5-aza-dC), calcein AM, and puromycin were purchased from Sigma.

Cell lines. The human colorectal cancer cell lines HCT116, SNU1040, DLD1, SW480, FET, COLO32 and HT29, the human breast epithelial cell line MCF10A, and the human embryonic kidney cell line 293T were obtained from the American Type Culture Collection and cultured according to their protocols.

Real-time PCR analysis. Total RNA was prepared with TRIzol reagent and cDNA was generated with SuperScript II reverse transcriptase (Invitrogen), followed by real-time PCR as described (17). Primer pairs used were PDLIM2, forward 5′-GCCCATCATGTTGAAGGAAG; reverse 5′-ATGGCCACGATATTGTCTCC; β-actin, forward 5′-ATCAAGTCATTGTCTCCCT; reverse 5′-GAGAGCGAGGCCAGATGGA; DNMT1, forward 5′-GGTTCTTCCCTCCCTGGAGAATGTC, reverse 5′-GGCCACGGCCGTACTG; DNMT3a, forward 5′-GGTTCTTCCCTCCCTGGAGAATGTC, reverse 5′-GGCCACGGCCGTACTG; DNMT3b, forward 5′-GGTGCTCCTCCTGAGCTC, reverse 5′-GGTCCAGGCAATAGCAGACT.

Cell growth assays. Cells were seeded into 12-well plates at a density of 5,000 cells per well, followed by 5-aza-dC (5 μmol/L) or vehicle treatment. The drug-containing medium was replenished every day. Cell density was determined by replacing the medium with 2 μmol/L of calcein AM in 1× dissociation solution (Treven) at the indicated time points. After 1 h of incubation, diesterase activity (relative fluorescence units) was measured with a Tecan Infinite 200 Microplate Reader, using an excitation wavelength of 485 nm and emission wavelength of 520 nm (18).

Bisulfite genomic DNA sequencing. Genomic DNA from 5-aza-dC-treated or mock-treated cells was isolated using the PureLink Genomic DNA Purification Kit (Invitrogen). Genomic DNA aliquots were then treated with sodium bisulfite using the EZ DNA Methylation-Gold Kit (Zymo Research), followed by PCR to amplify the PDLIM2 promoter using Hot-Start Taq enzyme (Qiagen). Primers designed to recognize the bisulfite-modified regions (-1084 to -800) of the PDLIM2 promoter were forward 5′-AGGAGTTTATATAATTTAG, reverse 5′-TACCTAAACAACCTCCTCC. The PCR products were then directly used for DNA sequencing or subcloned into the SmaI restriction site of pEGFP-N2 (Clontech) for single colony sequencing to determine the methylation status of the CpG dinucleotides within the PDLIM2 promoter.

Luciferase gene reporter assays. The indicated colon cancer cell lines were transfected with a x-b-TATA luciferase reporter plasmid in the presence of increasing amounts of Myc-PDLIM2. At 40 h posttransfection, luciferase activity was measured as described before (15). The expression of the Myc-PDLIM2, p65, and Hsp90 proteins was detected by direct immunoblotting assays. To reduce background, we used the cytoplasmic extraction for p65 detection.

Results and Discussion

Retroviral transduction and generation of stable transfectants. Human embryonic kidney 293T cells were transfected with pQCXIP-myc-PDLIM2, followed by viral supernatant collection and infection of the indicated colorectal cell lines as described before (19). Stable transfectants were obtained by selection with puromycin.

Colony formation assays. Cell suspension in culture medium containing 0.6% SeaPlaque low-melting agarose was added to plates coated with an initial underlay of 1% agarose in culture medium. Colony growth was scored after 21 d.

In vivo tumorigenicity assays. Five-week-old female severe combined immunodeficiency mice (Charles River) were challenged subcutaneously in the lower back with control or modified colorectal cancer cell lines as indicated. The recipient mice were sacrificed for tumor evaluation 14 d postinjection.

PDLIM2 expression is repressed in human colon cancer cells. Given the causative role of NF-κB in colon tumorigenesis and the involvement of PDLIM2 in the termination of NF-κB activation, we hypothesized that PDLIM2 may be involved in the pathogenesis of colon cancer. To test the
hypothesis, we examined the expression levels of PDLIM2 in different colon cancer cell lines, as PDLIM2 expression has recently been found to be repressed by the human T-cell leukemia virus type I (HTLV-I), the etiologic agent of adult T-cell leukemia (15). Indeed, PDLIM2 protein levels were much lower in all colon cancer cell lines we examined, compared with those observed in MCF10A, a nontumorigenic epithelial cell line (Fig. 1A). In correlation with protein down-regulation, PDLIM2 mRNA levels were also significantly decreased in these colon cancer cell lines (Fig. 1B). These data

![Figure 2. PDLIM2 repression in colon cancer cells involves DNA methylation. A, RNA levels of DNMT1, DNMT3a, and DNMT3b in the indicated colon cancer cells were analyzed by real-time PCR using β-actin mRNA level as a control and represented as fold induction in mRNA abundance relative to those in MCF10A cells (set as 1). Columns, mean; bars, SD (n = 3). B, the indicated cell lines were treated with the DNMT inhibitor 5-aza-dC (5 μmol/L) for 48 h, followed by real-time PCR to determine relative mRNA levels of PDLIM2. Changes in PDLIM2 mRNA abundance following 5-aza-dC treatment are represented as fold induction relative to those observed in an RNA sample from mock-treated cells. C, the indicated colon cancer cell lines were treated with 5 μmol/L 5-aza-dC or vehicle for the indicated time points, followed by cell growth assay. D, the indicated cell lines were treated with 5 μmol/L 5-aza-dC or vehicle for 5 d, followed by bisulfite genomic DNA sequencing as described in Materials and Methods. Each circle represents a CpG site; open circles represent unmethylated CpG dinucleotides whereas filled circles represent methylated CpG sites. The ratios of the filled areas in circles represent percentiles of the methylation in the CpG sites. The position of each CpG nucleotide relative to the PDLIM2 transcription initiation site (+1) is indicated at the top.](cancerres.aacrjournals.org)
indicate that PDLIM2 is repressed at both RNA and protein levels in human colon cancer cells.

**PDLIM2 repression in colon cancer cells involves DNA methylation.** To investigate the mechanism of PDLIM2 repression in colon cancer cells, we examined the potential role of DNA methylation, one major mechanism responsible for the repression of tumor suppressor genes in neoplastic cells (17). To do so, we examined the expression levels of DNMT1, DNMT3a, and DNMT3b, three DNA methyltransferases responsible for DNA methylation. Compared with their expressions in nontumorigenic epithelial cells, all three enzymes were consistently and significantly upregulated in each colon cancer cell line, although to different extents (Fig. 2A).

To establish a connection between DNA methyltransferase upregulation and PDLIM2 expression, we examined the effect of 5-aza-dC, a highly specific DNA methyltransferase inhibitor, on PDLIM2 expression in these cancer cells. In agreement with our recent finding that HTLV-I–mediated repression of PDLIM2 is mediated by DNA methylation (17), 5-aza-dC treatment efficiently restored PDLIM2 expression in all seven colon cancer cell lines examined (Fig. 2B). These data suggest that like HTLV-I–mediated repression, PDLIM2 repression in colon cancer cells also involves DNA methylation.

In association with the recovery of PDLIM2 expression, 5-aza-dC treatment also led to the growth inhibition of different colon cell lines (Fig. 2C; Supplementary Fig. S1). On the other hand, normal epithelial cells were largely resistant to the 5-aza-dC treatment (Supplementary Fig. S2). These data were consistent with the fact that 5-aza-dC is toxic to cancer cells but not normal cells both in vitro and in vivo (17, 20). Because 5-aza-dC showed efficient antitumor activity in phase III clinical trials for patients with myelodysplastic syndrome/acute myelogenous leukemia (20), these studies not only substantiate PDLIM2 epigenetic repression but also suggest a potential therapeutic strategy for human colon cancer. Clearly, the effect of 5-aza-dC cannot only be attributed to the reactivation of PDLIM2. Other yet to be identified targets of this antitumor drug may also play very important roles in colon cancer growth inhibition.

**Figure 3.** PDLIM2 inhibits NF-κB constitutive activation in colon cancer cells. A to D, the indicated colon cancer cell lines were transfected with κb-TATA–driven luciferase reporter in the presence of increasing amounts of Myc-PDLIM2, followed by luciferase assay. The luciferase activities were presented as the percentile of that in cells without Myc-PDLIM2 transfection (denoted as 100). The protein expression levels of Myc-PDLIM2, p65, and Hsp90 were detected by direct immunoblotting assays. *, nonspecific bands.
To investigate whether the PDLIM2 promoter is methylated in colon cancer cells and whether 5-aza-dC–mediated recovery of PDLIM2 expression involves the reverse of methylation of the PDLIM2 promoter, we performed bisulfite genomic DNA sequencing. As shown in Fig. 2D, the PDLIM2 promoter was hypermethylated in colon cancer cell lines, in comparison with normal control cell line. As expected, treatment of 5-aza-dC induced a dramatic decrease in methylation of the PDLIM2 promoter. These data strongly suggest that promoter methylation directly controls the expression of PDLIM2.

**PDLIM2 re-expression prevents constitutive activation of NF-κB in colon cancer cells.** To establish a mechanistic

![Figure 4. PDLIM2 re-expression suppresses the tumorigenicity of colorectal cancer cell lines.](image)

A and B, DLD1 and HCT116 colon cancer cells stably expressing Myc-PDLIM2 or an empty vector were plated in soft agar and colony numbers were counted at day 21 after plating. Columns, mean; bars, SD (*, P < 0.01). C and D, the DLD1 and HCT116 stable cell lines were subcutaneously inoculated into the lower back of severe combined immunodeficient mice. The mice were sacrificed at day 14 after inoculation and tumor weights were measured. Columns, mean; bars, SD (**, P < 0.05).
connection between PDLIM2 epigenetic repression and NF-κB in colon tumorigenesis, we performed luciferase gene reporter assays to examine the effect of PDLIM2 restoration on the constitutive activation of NF-κB in human colon cancer cells. As shown in Fig. 3A to D, PDLIM2 re-expression resulted in a dose-dependent suppression of NF-κB activation in four independent colorectal cancer cell lines, which was associated with decreased p65 expression. Our mechanistic studies further indicated that PDLIM2 shuttled p65 into the nuclear matrix for the proteasomal degradation in these colorectal cancer cells (Supplementary Fig. S3). These data imply that PDLIM2 repression is one important mechanism contributing to the constitutive activation of NF-κB in colon cancer cells.

PDLIM2 re-expression suppresses anchorage-independent growth and tumor formation of malignant colon cancer cells.

To investigate the significance of PDLIM2 repression in colon tumorigenesis, PDLIM2 was stably expressed in the colorectal cancer cell lines HCT 116 and DLD1 (Supplementary Fig. S4). We then measured soft agar colony forming activity in comparison to the control cells transduced with an empty vector. As expected, the colon cancer cell lines readily formed colonies, indicative of their anchorage-independent growth potential (Fig. 4A and B). However, the colon cancer cell lines stably expressing PDLIM2 formed far fewer and much smaller colonies in soft agar. These data suggest that PDLIM2 suppresses the tumorigenicity of colon cancer cells in vitro.

To confirm the in vitro studies in vivo, we subcutaneously injected the control and PDLIM2-expressing colon cancer cell lines into opposite flanks of individual severe combined immunodeficient mice. As shown in Fig. 4C and D, both control and PDLIM2 stable colon cancer cell lines developed tumors at the injection sites in mice. However, the tumors formed by the PDLIM2-expressing colon cancer cell lines were significantly smaller than those formed by the vector control cell lines. These results indicate that PDLIM2 suppresses the tumorigenicity of colon cancer cells in vivo.

Recent biochemical, pharmacologic, and genetic studies from both humans and animals strongly support a causative role for NF-κB in intestinal inflammation–associated tumorigenesis (4–10). However, the mechanisms by which NF-κB is constitutively activated during intestinal pathogenesis are largely unclear. Data presented in this study indicate that one important mechanism of NF-κB constitutive activation involves PDLIM2 repression via epigenetic silencing. Importantly, the DNA methyltransferase inhibitor 5-aza-dC not only reactivates PDLIM2 expression in multiple human colorectal cancer cell lines, but also reverts their tumorigenic phenotype. Although this antitumor drug also reverses promoter methylation of genes other than PDLIM2, specific re-expression of PDLIM2 alone is able to suppress the tumorigenicity of the malignant colon cancer cells both in vitro and in vivo. These data therefore provide mechanistic insights into colon tumorigenesis and a potential therapeutic strategy for human colon cancer.

Our data also suggest a novel tumor suppression role for PDLIM2. In support of this, our recent studies have shown that PDLIM2 is repressed epigenetically by HTLV-I (17). Similarly, PDLIM2 repression is one important mechanism of HTLV-I–mediated adult T-cell leukemias (15). In addition to colon cancer and adult T-cell leukemia, our more recent data suggest that PDLIM2 is repressed in certain other cancer types including breast cancer (21). It is noteworthy that the pathogenesis of these PDLIM2 repression–associated cancers has already been linked to NF-κB, suggesting a common tumor suppressor function of PDLIM2.
