**PD-1/PD-L1 Interactions Contribute to Functional T-Cell Impairment in Patients Who Relapse with Cancer After Allogeneic Stem Cell Transplantation**

**Abstract**

Tumor relapses remain a serious problem after allogeneic stem cell transplantation (alloSCT), despite the long-term persistence of minor histocompatibility antigen (MiHA)-specific memory CD8^+^ T cells specific for the tumor. We hypothesized that these memory T cells may lose their function over time in transplanted patients. Here, we offer functional and mechanistic support for this hypothesis, based on immune inhibition by PD-1/PD-L1 interactions. PD-L1 expression on myeloid leukemia cells, especially under inflammatory conditions, was highly upregulated on immature human leukemic progenitor cells, whereas costimulatory molecules such as CD80 and CD86 were not expressed. Thus, immature leukemic progenitor cells seemed to evade the immune system by inhibiting T-cell function via the PD-1/PD-L1 pathway. Blocking PD-1 signaling using human antibodies led to elevated proliferation and IFN-γ production of MiHA-specific T cells cocultured with PD-L1-expressing leukemia cells. Moreover, patients with relapsed leukemia after initial MiHA-specific T-cell responses displayed high PD-L1 expression on CD34^+^ leukemia cells and increased PD-1 levels on MiHA-specific CD8^+^ T cells. Importantly, blocking PD-1/PD-L1 interactions augmented proliferation of MiHA-specific CD8^+^ memory T cells from relapsed patients. Taken together, our findings indicate that the PD-1/PD-L1 pathway can be hijacked as an immune escape mechanism in hematological malignancies. Furthermore, they suggest that blocking the PD-1 immune checkpoint offers an appealing immunotherapeutic strategy following alloSCT in patients with recurrent or relapsed disease. *Cancer Res; 71(15): 5111–22. ©2011 AACR.*

**Introduction**

Alloreactive CD8^+^ T cells play a crucial role in the graft-versus-tumor (GVT) response following allogeneic stem cell transplantation (alloSCT) and donor lymphocyte infusion (DLI; ref. 1). In HLA-matched alloSCT, these alloreactive CD8^+^ T-cell responses are directed against minor histocompatibility antigens (MiHA; ref. 2). Previously, we have characterized CD8^+^ T-cell immunity toward a hematopoietic-restricted MiHA, designated LRH-1, which is presented by *HLA-B7* and encoded by the *P2×5* purinergic receptor gene (3). LRH-1-specific CD8^+^ T-cell responses can be frequently detected in myeloid leukemia patients following DLI, and has been associated with leukemic remission (3, 4). Moreover, we showed that CD34^+^ myeloid leukemia progenitor cells can be efficiently targeted *in vitro* by LRH-1-specific CD8^+^ CTLs, indicating that these CTLs play a significant role in graft-versus-leukemia (GVL)-specific immunity. However, we have observed that the presence of LRH-1–specific CD8^+^ memory T (T<sub>mem</sub>) cells for many years, late relapses do occur in patients with advanced myeloid leukemia. Furthermore, we noted that LRH-1–specific CD8^+^ T<sub>mem</sub> cells do not always efficiently expand with recurrence of leukemia cells, suggesting that these T cells become functionally impaired.

Mechanisms exploited by tumor cells to inhibit CD8^+^ T-cell–mediated immunity include disruption of antigen presentation, downregulation of HLA molecules, and induction of immunosuppressive components such as programmed death-1 (PD-1) signaling (5, 6). PD-1 plays a crucial role in T-cell regulation in various immune responses and is involved in peripheral tolerance, autoimmunity, infection, and antitumor immunity (7). Elevated PD-1 expression on antigen-specific
CD8⁺ T cells in chronic viral infection has been recognized as hallmark for T-cell exhaustion resulting in diminished cytokine production, proliferation, and cytolytic activity upon antigen restimulation (8). PD-1 binds 2 ligands, PD-L1 (B7-H1; CD274) and PD-L2 (B7-DC; CD273; ref. 7). Although PD-L2 expression is mainly restricted to antigen presenting cells (APC) like dendritic cells (DC) and macrophages, PD-L1 is also expressed by many nonhematological cell types (7). Furthermore, PD-L1 can be expressed on multiple tumor types and its expression is elevated following IFN-γ exposure (9). PD-L1 molecules on tumor cells can deliver negative signals through PD-L1 to tumor-reactive CTL, thereby inhibiting antitumor immunity (10). In agreement, PD-L1 expression has been associated with poor prognosis in various cancers including hepatocellular carcinoma and melanoma (9, 11). Notably, studies in models of murine myeloid leukemia have also shown that PD-1/PD-L1 interactions play an important role in immune evasion (12, 13). Interestingly, PD-L1 is also able to bind CD80, resulting in T-cell inhibition (14). Therefore, PD-L1 molecules on human leukemia cells may restrain CD8⁺ T-cell responses involved in GVL immunity after alloSCT.

In this study, we examined the role of PD-1/PD-L1 interactions in functional impairment of MiHA-specific CD8⁺ T cells. We observed that PD-L1 on myeloid leukemia cells is induced following IFN-γ and TNF-α exposure. Furthermore, we observed that activated LRH-1–specific CD8⁺ T cells express PD-1 during the course of the immune response. Importantly, we showed that blockade of PD-1/PD-L1 interactions using clinical grade human antibodies increases the proliferation and IFN-γ production of MiHA-specific CD8⁺ T cells when stimulated with PD-L1–expressing acute myelogenous leukemia (AML) cells and DC. Together, these findings indicate that the PD-1 signaling pathway suppresses MiHA-specific CD8⁺ T-cell responses and PD-1 blockade may be an attractive approach to boost GVL immunity in patients with recurrent or relapsed disease.

Materials and Methods

Patient and donor material

Peripheral blood (PB) and bone marrow (BM) samples of leukemia patients have been collected after written informed consent in ongoing clinical SCT protocols approved by the RUNMC Institutional Review Board. We used PB mononuclear cells (PBMC) obtained from transplanted patients who developed MiHA-specific CD8⁺ T-cell responses. Patient 1 (Pt 1) suffered from accelerated phase (AP) chronic myeloid leukemia (CML) and was successfully treated with therapeutic DLI after alloSCT (3). However, the patient relapsed 4 years after DLI. Patient 2 (Pt 2) suffered from AML and developed an LRH-1–specific CD8⁺ T-cell response upon preemptive DLI, but developed extramedullary relapses without leukemic involvement in BM (4). Characteristics of these and other transplanted patients are included in Table 2.

DCs were generated from monocytes isolated from PBMC of healthy donors by plastic adherence. Immature DCs (iDC) were generated by culturing adherent monocytes in X-VIVO 15 medium (Lonza) supplemented with 2% HS, 500 U/mL interleukin (IL)-4, and 800 U/mL Granulocyte macrophage colony-stimulating factor (GM-CSF) (both Immunotools). After 3 days, cells were harvested, used for T-cell stimulation experiments or further cultured as described before (15). At day 8, mature DCs (mDC) were harvested and used in T-cell stimulation experiments. LRH-1–specific CD8⁺ CTL culture RP1 was isolated from CM-LAP Pt 1 and was cultured as described previously (4). Before use in T-cell stimulation experiments, leukemia samples and DCs were cultured overnight with or without 100 U/mL IFN-γ and 1.25 ng/mL TNF-α (both Immunotools).

Mixed lymphocyte AML reactions and CTL stimulation assays

After culturing and preincubation, AML cells and DCs were washed, counted, and seeded in 96-well round bottom plates (Corning Costar). In lymphocyte AML reaction assays, allogenetic CD3⁺ T cells were isolated by direct magnetic labeling with the appropriate MicroBeads (Miltenyi Biotec) following the manufacturer’s instructions. Subsequently, 10⁵ CD3⁺ T cells were added to AML cells and mDCs at different E:T ratios. In MiHA-specific T-cell expansion assays, PD-L1 iDCs were loaded with 10 μmol/L LRH-1 peptide TP[NQ][RQ]NVC for 30 minutes at room temperature and cocultured with LRH-1–specific CTL RP1 at a stimulation ratio of 10:1.

Blocking antibodies were added at a final concentration of 10 μg/mL Antibodies to PD-1 (BMS-936558; MDX-1106; and ONO-4538) and PD-L1 (BMS-936559 and MDX-1105) and a matching immunoglobulin (Ig) G4 isotype control were kindly provided by Dr. A. Korman (Bristol-Myers Squibb, Biologics Discovery). BMS-936558 and BMS-936559 are genetically engineered, fully human IgG4 antibodies currently evaluated in clinical trials for selected tumor treatments (16). All cocultures were performed in a total volume of 200 μL Iscove’s modified Dulbecco’s medium (IMDM)/10% HS. After 5 days of coculture, supernatant was removed and fresh IMDM/10% HS containing 50 U/mL IL-2 and 5 ng/mL IL-15 (Immunotools) was added. At day 7, cells were harvested, counted, and the percentage of MiHA-tetramer⁺ CD8⁺ T cells was determined.

Flowcytometry

Expression of co-signaling ligands on myeloid leukemia cells and DCs was analyzed by staining with the following fluorochrome-conjugated antibodies: CD14 (Dako), CD3,
PD-1 Signaling Impairs MiHA-Specific CD8⁺ T Cells

CD34, CD117, CD54, CD80, CD83, CD86 (all from Beckman Coulter), anti-PD-L1, anti-PD-L2 (both from Becton Dickinson), and isotype controls IgG1 FITC/PE dual-color control (Dako) and IgG2b PE (Beckman Coulter). PD-1 expression on and the percentage of MiHA-specific CD8⁺ T cells were determined as described previously (15) using anti-PD-1 (Becton Dickinson). Cells were analyzed using the Coulter FC500 flow cytometer (Beckman Coulter).

Immunohistochemistry staining

Paraffin-embedded chloroma tissues were stained as previously described (17). Briefly, antigen retrieval was done using 10 minutes of boiling in 0.01 mol/L of sodium citrate pH 6.0 followed by incubation with primary antibodies anti-PD-L1 (eBioscience), anti-PD-L2 (eBioscience), anti-CD8 (DAKO), anti-CD34 (Klinipath), and anti-FoxP3 (ITK Diagnostics). Staining was visualized either by 3,3-diaminobenzidine (DAB) or aminoethyl carbazole (AEC) staining.

IFN-γ and granzyme B ELISA

Production of IFN-γ and granzyme B by stimulated T cells was determined by enzyme-linked immunosorbent assay (ELISA; IFN-γ: Pierce Endogen; granzyme B: Mabtech) according to manufacturer’s protocol.

Real-time quantitative reverse transcription PCR and microarray analysis

Total RNA was isolated from cell samples using Trizol (Invitrogen). cDNA synthesis and PCR amplification were carried out as described (18). The hydroxymethylbilane synthase (HMBS) housekeeping gene was used to normalize PD-L1 and PD-L2 expression. PD-L1 and PD-L2 mRNA expression is shown in ΔΔCt values and was quantified relative to cell line U266, which was set at 1 ΔΔCt value. ΔΔCt was calculated as follows: 2^[(-ΔCt_sample) - (ΔCt_U266)], in which ΔCt was normalized for HMBS by calculating ΔCt = Ct_gene - Ct_HMBS per sample.

For microarray analysis, LRH-1-tetramer⁺ human CD8⁺ T cells were sorted (median sorted cell number = 1,300; range 200–15,000 cells) on an Epics Elite sorter (Beckman Coulter), resulting in a more than 96% pure product, and resuspended in Trizol. RNA extraction, amplification, cDNA generation, and microarray analysis were done as described previously (19).

Statistical analysis

Paired 1-tailed student t test or 1-way ANOVA followed by a Bonferroni post hoc test was used when appropriate.

Results

Myeloid leukemia progenitor cells differentially express PD-L1 compared with CD80 and CD86

To investigate whether myeloid leukemia cells in relapsed patients after alloSCT express PD-L1 under inflammatory conditions, we analyzed leukemia samples from 2 patients who relapsed despite circulating LRH-1-specific CD8⁺ T cells (Table 1). We found that CD34⁺ CML-AP cells from a relapsed patient (Pt 1) at 4 years after DLI express PD-L1 upon

Myeloid leukemia cells express PD-L1 under inflammatory conditions. Expression of co-signaling ligands on leukemia cells was determined by FCM, immunohistochemistry, and RT-PCR. A, FCM analysis of PD-L1, PD-L2, CD80, and CD86 expression on CD34⁺ progenitor cells of CML-AP Pt 1 at time of relapse, 5 years after DLI. Leukemia cells were exposed to 100 IU/mL IFN-γ and 1.25 ng/mL TNF-α 16 hour before analysis. B, expression of PD-L1 and PD-L2 by CD34⁺ AML cells in a chloroma biopsy of Pt 2 at time of relapse, 3 years after DLI, was determined by immunohistochemistry. Staining was visualized using DAB (CD34) or AEC (PD-L1, PD-L2, and isotype control). Magnification 1,000/C2. C, CD33⁺ AML cells from 9 to 12 different patients were incubated with 100 IU/mL IFN-γ and 1.25 ng/mL TNF-α for 16 hours, after which PD-L1 and PD-L2 mRNA expression with (+) and without (-) IFN-γ and TNF-α was measured. D, expression of costimulatory ligands on CD33⁺ AML cells, in the absence (-) or presence (+) of IFN-γ and TNF-α, was determined by FCM. E, expression of PD-L1, PD-L2, CD80, CD86, and CD54 on CD33⁺CD117⁺CD14⁺ progenitor AML cells from 8 patients. Expression is depicted as mean ± SD. Paired 1-tailed student t test was performed. *, P < 0.05; **, P < 0.01; ***, P < 0.001.
Figure 2. PD-1 blockade enhances T-cell responses to stimulation by primary AML cells and DCs. Allogeneic CD3\(^+\) T cells were cocultured with PD-L1–expressing leukemia cells of AML Pt 9 (A) and (C) or PD-L1\(^+\)PD-L2\(^+\) mDC (B) and (D) with addition of blocking anti-PD-1 or anti-PD-L1 antibodies. Proliferation was measured on day 5 (A) and (B) and IFN-\(\gamma\) production was evaluated (C) and (D). LRH-1–specific CTL RP1 was cocultured with peptide-loaded primary leukemic cells of AML Pt 11 (E), (G), and (I) or peptide-loaded PD-L1\(^+\) iDC (F), (H), and (J), combined with blockade of PD-1 or PD-L1. Subsequently, proliferation was measured (E) and (F) in addition to IFN-\(\gamma\) production (G) and (H). Cytotoxicity was measured by granzyme B secretion (I) and (J). One representative experiment of 3. One-way ANOVA was performed compared with isotype antibody as control. *, \(P < 0.05\); **, \(P < 0.01\); ***, \(P < 0.001\).
inhibited with anti-PD-1 (Fig. 2B). This difference can be explained by the high PD-L2 expression on mDC resulting in insufficient interference of PD-1 signaling by the PD-L1 antibody. In agreement with the T-cell proliferation data, IFN-γ production was also increased by blocking of PD-1 interactions between T cells and PD-L1+ AML cells (Fig. 2C) or PD-L1+/L2+ mDC (Fig. 2D). These results show that PD-1 expression on AML cells decreases T-cell proliferation and cytokine production.

**MiHA-specific CTL expansion and function is enhanced by PD-1 blockade**

To elucidate the role of PD-1 on AML cells in inhibiting the recognition by MiHA-specific CD8+ T cells, we performed antigen restimulation experiments using CTL clone RP1 that recognizes the hematopoietic-restricted MiHA LRH-1 on AML progenitor cells (4). RP1, as well as CTls against other MiHA, upregulates the expression of PD-1 upon coculture with MiHA+ AML (Supplementary Fig. S3 and data not shown). Antibody blockade of PD-1 signaling using human antibodies resulted in improved proliferation and IFN-γ production by CTL RP1 upon engagement of PD-1–expressing AML cells from Pt 11 loaded with MiHA peptide (Fig. 2E and G). As hypothesized, we found that PD-1 blockade strongly elevated the proliferation and IFN-γ production by CTL RP1 when stimulated with peptide-loaded PD-L1+ iDC (Fig. 2F and H). Cytotoxicity of CTL versus AML was also enhanced after PD-1 and PD-L1 blockade (Fig. 2I), whereas no cytotoxicity was observed versus iDC (Fig. 2J). These data indicate that MiHA-specific CD8+ effector T cells can be inhibited via the PD-1/PD-L1 pathway either by AML or resident APC populations that selectively express PD-1 in the leukemia microenvironment.

**PD-1 is highly expressed by circulating MiHA-specific CD8+ T cells in vivo**

Next, we investigated whether PD-1 is expressed by LRH-1–specific T cells in CML-AP Pt 1 and AML-M0 Pt 2 who relapsed 3 and 4 years, respectively, after the initial DLIIs that induced long-lasting LRH-1–specific CD8+ T-cell responses in these patients. PD-1 expression could be detected on LRH-1–specific CD8+ T cells during the complete course of the immune response after DLI which peaked at peak 28 for CML-AP Pt 1 and at week 10 for AML-M0 Pt 2 (Fig. 3A). We observed relatively elevated expression of PD-1 on LRH-1–tetramer-positive T cells compared with tetramer-negative CD8+ T cells in the same patient (Fig. 3A and B). After DLI, PD-1 levels at the cell surface of LRH-1–specific CD8+ T cells gradually declined, but more than 95% of the tetramer-positive T cells remained PD-1 positive during the contraction phase. To determine PD-1 expression of the apparently impaired LRH-1–specific CD8+ Tmem cells in the relapsed patients several years after DLI, we sorted LRH-1–specific CD8+ T eff cells (Pt 1: 1.8% at week 28; Pt 2 2.9% at week 15) and low frequencies of LRH-1–specific CD8+ Tmem cells (Pt 1: 0.08% at week 225; Pt 2 0.05% at week 151) and performed microarray analysis using amplified cDNA. PD-1 mRNA levels of LRH-1–specific CD8+ Tmem cells at the time of relapse were elevated or similar compared with LRH-1–specific CD8+ T eff cells at the peak of the response for Pt 1 and Pt 2, respectively (Fig. 3C). These data indicate that LRH-1–specific CD8+ T cells express elevated levels of PD-1 on the cell surface, which remain present during the contraction and late memory phase of the immune response following DLI.

**PD-1 blockade augments proliferation of MiHA-specific CD8+ T cells**

To further elucidate the role of PD-1 in impairment of LRH-1–specific CD8+ Tmem cells, we performed functional assays using PBMCs from CML-AP Pt 1 containing 0.05% to 0.10% LRH-1–specific CD8+ Tmem cells several years after the initial response. Stimulation of PBMC of Pt 1 with peptide alone in the presence of IL-2 and IL-15 did not result in an increase of LRH-1–specific T cells (data not shown). Notably, PD-1 or PD-L1 blockade resulted in a 2- to 4-fold increase in the number of LRH-1–specific T cells (Fig. 4A). However, peptide stimulation in the presence of PD-1 blockade, but in the absence of professional APCs, resulted in insufficient T-cell outgrowth. Therefore, we stimulated PBMCs containing LRH-1–specific Tmem cells with peptide-loaded PD-L1–expressing iDC in the presence of PD-1 blockade. Blockade with anti-PD-1 antibody resulted in a 20 times higher number of LRH-1–specific CD8+ T cells after 3 stimulations with peptide-loaded PD-L1+ iDCs (Fig. 4B). Consistently, we observed a specific increase to 4.4% LRH-1–specific CD8+ T cells compared with 0.6% with the isotype control after repeated DC stimulations using blockade with anti-PD-1 (Fig. 4C).

Similar assays were performed with PBMC obtained 7 and 36 months post-DLI containing low numbers of LRH-1–specific Tmem cells from AML-M0 Pt 2. In these assays, we used mDC to prevent repetitive T-cell stimulation. At 7 months post-DLI, blocking with anti-PD-1 and anti-PD-L1 antibody resulted in increased outgrowth of LRH-1–specific CD8+ T cells up to 8.1% and 6.4%, respectively, compared with 2.0% in the presence of an isotype control (Fig. 4D). In addition, during relapse at 36 months post-DLI, upon PD-1 and PD-L1 blockade LRH-1–specific CD8+ T cells increased to 1.16% and 0.86%, respectively, compared with 0.59% for isotype control (Table 2). To confirm effect of PD-1/PD-L1 blockade on the proliferative capacity of other MiHA-specific T cells, we stimulated PBMC from a relapsed multiple myeloma (MM) patient (Pt 16) containing HAA–specific T cells. In concordance with results obtained with LRH-1–specific CD8+ T cells, blockade of PD-1/PD-L1 interactions led to enhanced DC-stimulated proliferation of HA–specific CD8+ T cells (Fig. 4E). In addition, we investigated whether PD-1 blockade increased the absolute amount of MiHA-specific T cells. For AML Pt 2 and MM Pt 16, we observed a robust absolute increase of MiHA-specific T cells upon PD-1 and PD-L1 blockade (Fig. 5A).

Next, we investigated whether the effect of PD-1/PD-L1 is exclusive for dysfunctional MiHA-specific T cells in relapsed patients, or that it also affects potential nonimpaired T cells in patients with remission after alloSCT. Therefore, we investigated the effect of PD-1/PD-L1 blocking in CML-BC Pt 15 and pre-T ALL Pt 17 (Table 2). PD-1 and PD-L1 blockade does enhance the absolute number of MiHA-specific T cells, but the
The effect is moderate (Fig. 5B). Finally, we compared the effect of PD-1 blockade on MiHA-specific T cells from relapsed patients to those from patients in remission. Importantly, we showed that PD-1 blockade has a significantly superior effect on dysfunctional MiHA-specific T cells from relapsed patients (Fig. 5C).

Collectively, these results show that PD-1 signaling impairs the proliferative capacity of MiHA-specific CD8\(^+\) T cells upon antigen stimulation prior to or during relapse, and this functional impairment can be abrogated by PD-1/PD-L1 immune checkpoint blockade.

**Discussion**

AlloSCT is a potentially curative treatment for advanced myeloid leukemia (1). The effect largely depends on alloreactive CD8\(^+\) T cells targeting MiHA on leukemic blasts and progenitor cells (20). However, MiHA-specific CD8\(^+\) T-cell responses induced after transplantation are in many patients not sufficient to sustain complete remission. Distinct mechanisms are involved in reducing antitumor T-cell responses, allowing malignant cells to escape immune destruction. Among these mechanisms, T-cell inhibition or even exhaustion due to signaling of the PD-1/PD-L pathway may diminish immune responses by limiting the expansion and functionality of CD8\(^+\) T cells (12, 21). Recently, we showed that LRH-1 leukemia can relapse without inducing secondary LRH-1-specific CD8\(^+\) T\(_{\text{mem}}\) cell expansion, suggesting that these T\(_{\text{mem}}\) cells are either suppressed or not activated (3, 4). In this study, we examined the role of PD-1/PD-L1 interactions in functional impairment of LRH-1-specific CD8\(^+\) T cells reactive to myeloid leukemia. Interestingly, we showed that PD-L1...
Figure 4. PD-1 blockade increases ex vivo proliferation of MiHA-specific CD8\(^+\) T\(_{mem}\) cells. A, PBMC of CML-AP Pt 1 containing low levels of LRH-1–specific T\(_{mem}\) cells years after initial responses were stimulated by addition of LRH-1 peptide in the presence of blocking antibodies against PD-1 or PD-L1. Numbers of LRH-1–specific cells were enumerated by FCM, and numbers at isotype control were set to 1. Results are from 3 independent experiments from a sample 225 weeks after DLI (\(\sim\), and *) and 1 sample taken 275 weeks after DLI (!). B, iDCs were loaded with LRH-1 peptide and added weekly to PBMC containing LRH-1–specific T\(_{mem}\) cells for 3 weeks, combined with blocking antibodies. C, LRH-1–specific T-cell percentages of total CD8\(^+\) were identified by FCM. iDC stimulation assays with Pt 1 are representative of 3 separate experiments. D, mDCs loaded with LRH-1 peptide were used to stimulate LRH-1–specific T\(_{mem}\) cells of AML-M0 Pt 2. Subsequently, the percentage of LRH-1–specific T cells after 1 week was determined by FCM. E, mDCs loaded with HA-1 peptide were used to stimulate HA-1–specific T\(_{mem}\) cells of relapsed MM Pt 16. Subsequently, the percentage of HA-1–specific T cells after 1 week was determined by FCM.
and to some extent, PD-L2 was expressed by CD34$^+$ progenitor myeloid leukemia cells of 2 patients with relapses after initial efficient T-cell responses. Furthermore, we confirmed expression of PD-L1 on a broader panel of AML samples at diagnosis. Previously, it has been shown that PD-L1 expression is elevated on relapse AML compared with diagnosis material (22). We investigated this in 1 CML patient, and indeed, PD-L1 expression was higher on relapse tumor cells than cells at diagnosis (Table 1). Especially, CD117$^+$ CD14$^-$/CD10$^-$ early progenitor myeloid leukemia cells, which contain the leukemic stem cells, highly expressed PD-L1. PD-L1 expression increased upon exposure to inflammatory cytokines, whereas expression of CD80 and CD86 remained low. Consequently, prolonged PD-1/PD-L1 interactions may lead to functional exhaustion of LRH-1$^-$ specific Tmem cells, and relapse of the leukemia may occur without induction of a secondary immune response.

To investigate whether LRH-1$^-$ specific T cells display an impaired phenotype, we analyzed T cells of 2 patients with LRH-1$^-$ specific responses. It is known that PD-1 is elevated on T cells specific for viral epitopes in chronic viral infections (23). Also, during CML disease, PD-1 levels of the total population of CD8$^+$ T cells are elevated (12). Here, we showed for the first time that MiHA-specific Tmem cells can have an elevated level of PD-1. Both patients with the nonresponding Tmem cells had leukemia relapses following a robust initial LRH-1$^-$ specific T-cell response. Whether or not elevated PD-1 expression on MiHA-specific T cells correlates with immune escape and subsequent relapse of myeloid leukemia needs to

**Figure 5.** The effect of PD-1 blockade on proliferation of MiHA-specific T cells in relapsed patients is higher than in patients in remission. PBMCs containing MiHA-specific T cells were stimulated with DC containing their cognate peptide with or without anti-PD-1 or anti-PD-L1. A, PD-1/PD-L1 blockade enhances the expansion of MiHA-specific T cells in relapsed patients. Pt 2 and 16 experienced relapse after initial MiHA-specific responses. PBMCs prior to additional therapy to treat relapse were investigated. B, PD-1/PD-L1 blockade moderately enhances the expansion of MiHA-specific T cells in patients in long-term remission. Pt 15 and 17 remained in remission after initial immune responses. C, the effect of PD-1 blockade is significantly higher on MiHA-specific T cells in relapsed patients. Ratio was calculated by dividing the absolute number of tet$^+$ T cells in the presence of anti-PD-1 antibody by the absolute number of tet$^+$ T cells in the presence of isotype control. One-tailed student t test was performed. *, P < 0.05.
be determined in a larger cohort of patients. However, we found that the PD-1/PD-L1 pathway negatively influences the function of PD-1-expressing LBR-1-specific CTL. Most importantly, we show that blocking PD-1/PD-L1 interactions with human blocking antibodies resulted in increased outgrowth of MiHA-specific T\textsubscript{mem} cells. We also observed a stimulatory effect of PD-1 blockade on MiHA-specific T cells from patients in remission, which is not unexpected due to the role of PD-1 in regulation of T-cell activation. However, the abrogation of PD-1 signaling had a significant stronger effect on the proliferation of MiHA-specific T cells in relapsed patients than those in patients in remission.

Besides PD-1, several other inhibitory receptors play a role in functional T-cell exhaustion, such as CTLA-4, LAG-3, BTLA, TIM-3, CD160, and CD244 (24). In future years, the influence of this array of coinhibitory receptors will be further elucidated. Perhaps, combinations of blocking antibodies to PD-1 and LAG-3 will result in highly reactivated MiHA-specific T-cell responses (25). But, as PD-1 is involved in peripheral tolerance, autoimmune events following PD-1 blockade therapy may occur (26). In a recent phase I study, the clinical grade anti-PD-1 antibody BMS-936558, also used in our study, was administered to patients with solid tumors. Anti-PD-1 was well tolerated and only 1 serious adverse event, inflammatory colitis, was observed in a melanoma patient. Remarkably, 1 durable complete response and 2 partial responses were observed (16).

Our current \textit{in vitro} data illustrate that PD-1 blockade is an attractive approach to reinvigorate impaired MiHA-specific T cells in patients with persisting or relapsed leukemia. However, in the setting of alloSCT, PD-1 blockade could aggravate GVHD. For optimal boosting of GVT immunity in the post-SCT setting, we would like to combine active immunotherapy by DC vaccination using hematopoietic-restricted MiHAs with PD-1 blockade. By inducing a time-limited allelotherapy by DC vaccination using hematopoietic-restricted MiHAs with PD-1 blockade. Therefore, we postulate that PD-1 blockade could be a powerful addition to post-SCT therapy. Combining MiHA-specific DC vaccination with PD-1 blockade may reinvigorate impaired MiHA-specific T\textsubscript{mem} cells and restore immune control, thereby preventing or attacking leukemia relapses.
