The LMP7-K Allele of the Immunoproteasome Exhibits Reduced Transcript Stability and Predicts High Risk of Colon Cancer

Barbara Fellerhoff1,5, Songhai Gu5, Barbara Laumbacher5, Andreas G. Nerlich6, Elisabeth H. Weiss7, Jürgen Glas2,3, Reinhard Kopp4, Judith P. Johnson1, and Rudolf Wank5

Abstract

Destruction of cancer cells by cytotoxic T lymphocytes depends on immunogenic tumor peptides generated by proteasomes and presented by human leukocyte antigen (HLA) molecules. Functional differences arising from alleles of immunoproteasome subunits have not been recognized so far. We analyzed the polymorphism of the immunoproteasome subunits LMP2 and LMP7 and of the transporters associated with antigen processing (TAP1 and TAP2) in two independently collected panels of colorectal carcinoma patients (N1 = 112, N2 = 62; controls, N = 165). High risk of colon cancer was associated with the LMP7-K/Q genotype (OR = 8.10, P = 1.10 × 10−15) and low risk with the LMP7-Q/Q genotype (OR = 0.10, P = 5.97 × 10−15). The basis for these distinct associations of LMP7 genotypes was functionally assessed by IFN-γ stimulation of colon carcinoma cell lines (N = 10), followed by analyses of mRNA expression of HLA class I, TAP1, TAP2, and LMP7, with real-time PCR. Whereas induction of HLA-B, TAP1, and TAP2 was comparable in all cell lines, transcript amounts of LMP7-Q increased 10-fold, but of LMP7-K only 3.8-fold. This correlated with a reduced transcript stability of LMP7-K (t1/2 ≈ 7 minutes) compared with LMP7-Q (t1/2 ≈ 33 minutes). In addition, LMP7-Q/Q colon carcinoma cells increased (the peptide based) HLA class I surface expression significantly after IFN-γ stimulation, whereas LMP7-Q/K and LMP7-K/K carcinoma cells showed minimal (<20%) changes. These results suggest that the presence of LMP7-K can reduce the formation of immunoproteasomes and thus peptide processing, followed by reduced peptide–HLA presentation, a crucial factor in the immune response against cancer.

Cancer Res; 71(23); 7145–54. ©2011 AACR.

Introduction

Genetic and environmental factors influence type and growth of malignant tumors. Numerous studies have found associations between particular human leukocyte antigen (HLA) alleles and an increased risk to develop cancer, and the loss of HLA expression by tumors has been associated with poor prognosis in many tumors (1, 2). The initiation of successful antitumor immune responses requires presentation of immunogenic tumor peptides by HLA classes I and II molecules (3). Efficient presentation of peptide–HLA complexes (pMHC) on the cell surface depends on the production and processing of the peptide. Proteasomes and immunoproteasomes process intracellular proteins into peptides, whereas selection and transport is carried out by the heterodimeric transporter associated with antigen processing (TAP; ref. 4). IFN-γ stimulation alters proteolytic activity and peptide generation of the proteasome through the incorporation of LMP2 (PSMB9) and LMP7 (PSMB8) subunits into newly assembling immunoproteasomes (5). The LMP-containing immunoproteasomes generate more and better fitting peptides than constitutive proteasomes (6).

The HLA informatics group and the Human Genome Organization (HUGO) Gene nomenclature committee established the actual name for LMP2 as PSMB9 [proteasome (prosome, macropain) subunit, β type, 9 (large multifunctional peptidase 2)] and for LMP7 as PSMB8 [proteasome (prosome, macropain) subunit, β type, 8 (large multifunctional peptidase 7; refs. 7, 8)].

Until now studies on dysregulation of antigen processing in cancer cells have focused on the loss or downregulation of TAP or LMP, which can lead to low expression or absence of the pMHC and thereby prevent activation of cytotoxic T lymphocytes (9, 10). Genetic polymorphisms have been identified in LMP7 and LMP2 as well as in the transporter proteins TAP1 and TAP2 (II–13). We hypothesized that the function of the
antigen processing and transport pathway might be influenced by structural differences encoded by TAP or LMP alleles and that particular alleles might be associated with increased tumor risk (9). To this end, we first assessed frequencies of TAP and LMP alleles in patients with colorectal carcinomas compared with healthy controls. Then, we analyzed cancer cells carrying cancer-associated alleles functionally. We compared inducibility of disease-associated LMP7 alleles and non-disease-associated LMP7 alleles following IFN-γ stimulation by quantifying LMP7 RNA transcripts and analyzing their stability. Finally, we also measured surface expression of HLA molecules in those cell lines.

Materials and Methods

Carcinoma samples, cell lines, and subjects

Historical samples from the large intestine of 112 unrelated Caucasian patients were diagnosed histologically as carcinomas and resected in the following locations: 4 in the cecum, 48 in the colon, 19 in the sigma, 18 in the rectosigmoidal part, and 23 in the rectum. Twenty-five samples of the colon and 11 of the sigma were snap frozen, all other samples were preserved in paraffin. A second independently collected panel from the Munich area consisted of 62 snap-frozen carcinoma samples, 9 from the cecum, 24 from the colon, 10 from the sigma, 2 from the rectosigmoidal part, and 17 from the rectum. Peripheral blood mononuclear cell (PBMC) from 165 randomly selected unrelated Caucasian individuals from the Munich area with previously defined HLA class I polymorphisms (14) were used as controls. For the control persons, the male/female ratio was 0.64 and age 33.6 ± 9.4 years; for the carcinoma patients, male/female ratio was 0.44 and age 69.6 ± 10.3 years. The control persons were free of disease at the time point of blood collection. No follow-up of the cohorts were available.

Cell lines WT100BIS and KAS116 as well as Caski and HeLa were obtained from the American Type Culture Collection and served as positive controls for the LMP-ARMS-PCRs and human papilloma virus (HPV)–specific PCRs, respectively. Colorectal carcinoma lines Colo205, HT29, CX1, WiDr, SW948, and Caco2 were obtained from the European Type Tissue Type Culture Collection. The colon carcinoma cell line WEB2 was established in the Institute of Immunology, Munich.

Cell culture

Colorectal cancer cell lines were cultured at 37°C and 5% CO2 in RPMI 1640 (Boehringer Ingelheim), supplemented with 10% fetal calf serum. For HLA expression, cancer cell lines were treated for 16 or 20 hours with 200 U/mL recombinant human IFN-γ (Imukin; Boehringer Ingelheim). Cells were harvested after 16 hours or appropriate time for mRNA-stability experiment) of incubation with or without IFN, centrifuged and immediately shock frozen in liquid nitrogen. Complete RNA was isolated using the QIAshredder and RNaseasy Kit including DNase digestion according to manufacturer’s instruction (QIAGEN). For reverse transcription of complete RNA, the RevertAid First Strand cDNA synthesis Kit including random hexamers was chosen, following manufacturer’s instruction (Fermentas).

All materials for the reverse transcription real time PCR were obtained from Applied Biosystems, using the TaqMan Universal PCR Master Mix, and the following predesigned gene expression assays: LMP7 exon 1 (Hs00188149_m1), LMP7 exon 3 (Hs00544758_m1), G6PDH endogenous control (Hs00166169_m1), 18S rRNA endogenous control, TAPI (Hs00184476_m1), TAP2 (Hs00241060_m1), and HLA-B (Hs00741005_g1). To detect the LMP7 allelic variation in exon 2, the oligonucleotides LMP7-E2-fw (5’-TCG GAC CCA GGA

LMP7-K Predicts Risk of Colon Cancer

Results

Analyses of immunogenetic polymorphisms

Frequencies of TAP alleles and genotypes were defined by sequence analysis (Supplementary Methods and Supplementary Tables S1 and S2), and frequencies of LMP alleles and LMP genotypes by ARMS-PCR in CRC patients (n = 174) and in controls (n = 165). LMP2 and LMP7 allele frequencies in controls were similar to population frequencies in North American Caucasians (12). No linkage disequilibrium between alleles of TAP, LMP, and MHC class I alleles were observed (data not shown), confirming the solidity of our control panel.

Neither TAPI/TAP2 allele (Supplementary Table S3) nor TAPI/TAP2 genotype frequencies (not shown) of CRC patients differed significantly from the frequencies observed in the control population. However, the immunoproteasome LMP7-K allele was significantly more often found in CRC patients than in controls (24.1% versus 6.1%; P = 2.52 × 10^{-11}, Table 1). Frequency deviations seemed to be associated with tumor location (Fig. 1), as the LMP7-K allele was found more often in patients with tumors of the proximal segment (colon) than in patients with tumors of the distal part (rectum; 31.9% versus 15.0%; Table 1). Nevertheless, the association with cancer patients remained significant for all bowel segments analyzed (Table 1). The second allele, LMP7-Q, was significantly more common in control individuals than in CRC patients. The distinct associations between LMP7-K and LMP7-Q alleles and CRC patients became obvious when comparing frequencies of the 3 possible genotype combinations, LMP7-K/K, LMP7-K/Q, and LMP7-Q/Q (Table 2). The LMP7-Q/Q genotype was significantly less frequent in CRC patients than in normal controls. We calculated a 10.0-fold reduced relative risk for colon carcinoma in LMP7-Q/Q homozygous individuals (OR = 0.10, P = 5.97 × 10^{-13}, Table 2, Fig. 1). The association of the LMP7-K allele with CRC susceptibility was dominant because CRC patients carried the LMP7-K/Q genotype 3 times more often than control individuals (40.2% versus 12.1%, P = 3.88 × 10^{-9}). The strength of association and relative risk values of the LMP7 genotypes were also significantly influenced by tumor location (Table 2, Fig. 1). Patients with distal tumors, that is, rectal (25.0%) and rectosigmoidal carcinomas (30.0%), carried the LMP7-K/Q genotype nearly twice as often as controls. Patients with more proximal tumor locations, that is, sigmoid carcinomas (41.4%), carried the LMP7-K/Q genotype 3 times more often, and those with the most proximal location, that is, colon carcinomas (52.8%), 4 times more often than controls (colon versus rectum carcinoma, P = 5.32 × 10^{-3}). The maximum OR revealed an 8.10-fold increased relative risk (P = 1.10 × 10^{-11}) for colon cancer in LMP7-K/Q heterozygous individuals (Table 2, Fig. 1).

Allele and genotype frequencies showed no gender preference

Frequencies of LMP2 alleles in patients did not deviate significantly from frequencies in controls (Table 1). The LMP2-H/H phenotype showed an increased frequency in patients with rectal carcinoma (15.0%; controls 6.7%; P > 0.05, Table 2).

Determination of mRNA stability by actinomycin D treatment

Cell culture cells were stimulated with IFN-γ-1b as described. Following the addition of 50 μg/ml actinomycin D, cells were kept under stimulation condition and samples were taken after 0 minute, 30 minutes, 1 hour, and 4 hours.

Western blot analysis

Polyacrylamide gel electrophoresis and Western Blot analysis were conducted according to established methods. The antibodies used were mouse monoclonal antibody clone LMP2-13 directed against 20S proteasome subunit LMP2 (ab78336; Abcam), mouse monoclonal antibody directed against 20S proteasome subunit LMP2 (ab58094; Abcam and IG7; Novus Biologicals), and mouse monoclonal antibody directed against β-actin (ab6276; Abcam). For detection, a horseradish peroxide (HRP)-conjugated secondary antibody was used (polyclonal rabbit anti-mouse immunoglobulins/HRP; P 0260; Dako); chemiluminescence detection was carried out with Lumi glow (LumiGLO, Cell signalling technology). The PageRuler Prestained Protein Ladder (Fermentas) served as molecular weight standard.

Statistical analysis

LMP and TAP allele frequencies were obtained by direct counting. Two-sided Fisher exact test was computed when a table had a cell with a less than an expected frequency of less than 5, otherwise 2-sided exact P values were used. To calculate P values, the computer program SPSS (version 10.1.3; SPSS GmbH Software) was used. The P values are 2-tailed on a 95% significance level. The relative risk (OR) was calculated according to the formula for ORs as: OR = (affected patients × unaffected controls)/(unaffected patients × affected controls). The 95% CI of the OR was calculated by the computer program SPSS (version 10.1.3). Cell lines CX-1 and WiDr are derivatives of HT-29. Both were excluded from calculations and statistical analyses.
Combined analysis of LMP2/LMP7 genotypes showed that neither the reduced risk of the LMP7-Q/Q genotype nor the increased risk of the LMP7-K/Q genotype was significantly altered by combinations with any of the LMP2 genotypes (Table 3). Therefore, we exclude that LMP2 could influence susceptibility in rectal carcinomas independently from LMP7 (Table 2).

To investigate, whether different tumor locations could reflect antigen processing of differentially located microbial factors as suggested for Helicobacter pylori in the proximal segment (17) or HPV in the distal segment of the large intestine (3), we used published PCR methods to detect H. pylori (18, 19) and HPV (20) in our samples (Supplementary Methods). We could not detect H. pylori DNA and only 5 of 100 samples tested were positive for HPV at a lower frequency than reported (3, 20–23).

### Functional differences between LMP7-Q/Q and LMP7-K/Q genotypes

Proteolytic activity and peptide generation by the proteasome are altered after IFN-γ stimulation by insertion of the LMP2 and LMP7 subunits into newly assembling immunoproteasomes (5).

To test for functional differences between LMP7-Q and LMP7-K, we examined their mRNA expression following IFN-γ stimulation. It must be stated, that the LMP7 polymorphism in this study is located in the presequence of LMP7 and is therefore absent in the mature protein. The polymorphism can therefore not affect the intrinsic enzymatic activity of LMP7, but can only affect the assembly of the immunoproteasome, either by reducing the level of LMP7 or by interfering with the complex process of assembly, which depends on the presequence. Using probes for

NOTE: This table gives LMP allele frequencies according to tumor localization. In addition, the relative risk (OR) values, significant P values, and CIs are stated. The OR values are positively associated with LMP7-K and inversely associated with LMP7-Q.

aOR = 4.93 (CI = 2.95–8.25), P = 2.52 × 10^{-11}, \( \chi^2 = 42.62 \) (all colorectal carcinoma patients vs. controls).
bOR = 7.28 (CI = 4.11–12.89), P = 1.04 × 10^{-10}, \( \chi^2 = 56.04 \) (colon carcinoma patients vs. controls).
cOR = 4.93 (CI = 2.32–10.46), P = 8.31 × 10^{-16}, \( \chi^2 = 20.16 \) (sigma carcinoma patients vs. controls).
dOR = 3.87 (CI = 1.58–9.50), P = 5.64 × 10^{-3}, \( \chi^2 = 9.91 \) (rectosigmoid carcinoma patients vs. controls).
eOR = 2.73 (CI = 1.28–5.86), P = 1.13 × 10^{-2}, \( \chi^2 = 7.15 \) (rectum carcinoma patients vs. controls).

Figure 1. Strength of association of LMP7 alleles with colorectal cancer. A, strength of association of LMP7 alleles with colorectal cancer given as relative risk values with regard to susceptibility (red column) or resistance (blue column). B, changing values of relative risk shown according to tumor localization.
exon 3 (E3), the LMP7 mRNA increased only weakly in LMP7-K/K homozygous cell lines, with a mean of 3.84-fold (± 2.85), compared with a mean of 10.08-fold (± 0.98) in LMP7-Q/Q homozygous cell lines (P < 0.05, U test; Fig. 2A). The LMP7-K/K heterozygous cell line showed an intermediate phenotype with an 8.23-fold induction of LMP7-E3. The probes for LMP7 exon 3 detect both of the 2 known splice variants LMP7-E1 (exon 1–exon 3) and LMP7-E2 (exon 2–exon 3; refs. 24, 25; Fig. 2C). Because efficient translation and incorporation has been detected only for LMP7-E2 (26), we also carried out real-time PCR for exon 2 with primers and probes distinguishing the 2 alleles. In addition, we examined the expression of exon 1 (LMP7-E1; Fig. 2A). In LMP7-Q homozygous cell lines, transcripts of LMP7-E1 were inducible with a mean of 3.56-fold (± 1.26) and transcripts of LMP7-E2 with a mean of 8.81-fold (± 0.61; Fig. 2A). In LMP7-K homozygous cell lines, the induction of LMP7-E1 and LMP7-E2 transcripts was weaker (LMP7-E1 mean 1.1-fold ± 0.92, LMP7-E2 mean 3.49-fold ± 2.43, P < 0.05, U test). Interestingly, the LMP7-K/Q heterozygous cell line showed a differential inducibility of the 2 alleles with a 7.68-fold induction for LMP7-E2-Q and 5.83-fold induction for LMP7-E2-K.

The reduced expression of LMP7 mRNA in LMP7-K/K cells was not associated with reduced induction of HLA-B or of the transporter subunits TAP1 and TAP2 as determined by real-time PCR (Fig. 2B), so that a general defect in the IFN-γ induction pathway in these cells can be excluded.

Analysis of LMP7 mRNA transcript stability

Because reduced mRNA levels could originate either from reduced transcription or from reduced transcript stability, we analyzed transcript stability with actinomycin D (Fig. 3). The half-life of the LMP7-mRNA was dramatically reduced in the 2 tested LMP7-K/K homozygous cell lines (CaCo2 t1/2 = 5.87 minutes, SW948 t1/2 = 8.23 minutes), compared with 2 LMP7-Q/Q homozygous cell lines (Colo320DM t1/2 = 28.09 minutes, HT29 t1/2 = 38.17 minutes). Therefore, we conclude that the presence of the lysin codon (AAG) at position 49 reduces the LMP7 mRNA stability by 75% (mean t1/2 = 7 minutes) of that observed for the glutamine coding LMP7-Q allele transcript (mean t1/2 = 33 minutes).

To investigate whether the lower level of LMP7 mRNA influences surface HLA class I expression, we analyzed HLA-A, B, C expression of 12 CRC cell lines before and after stimulation with IFN-γ (Fig. 4A and B). After stimulation with IFN-γ, all LMP7-Q/Q cell lines (Fig. 4C open circles) showed an increased relative MFI of at least 100%, whereas cell lines carrying the LMP7-K allele (Fig. 4C closed or dot-filled circles) showed at best an increase of 20% MFI.

### LMP7 protein detection in tumor tissue and cell lines

To add another evidence to our analysis, we investigated the amount of Lmp7 protein in tissues of colorectal carcinoma patients. Despite the limited samples, one major problem with this analysis is the fact, that Lmp7 is not a constitutively

---

Published OnlineFirst October 28, 2011; DOI: 10.1158/0008-5472.CAN-10-1883
expressed protein, but an IFNγ inducible subunit of the immune proteasome. Therefore, we did not expect to detect Lmp7 protein in all tissue samples, but rather we expected only a few specimens to be positive in the Western Blot analysis. Samples positive for β-actin protein were excluded from the analysis. Out of the 5 tested samples homozygous for LMP7-K, none showed a signal with the LMP7-specific antibody, whereas 2 were positive for LMP2. Testing 20 samples of heterozygote patients also showed no positive signal for Lmp7 protein, but Lmp2 protein was detected in 6 samples. The samples of the LMP7-Q/Q homozygote patients showed a signal for LMP7 in 14 out of 32 tested specimens, and the same samples also showed a signal after re-probing the blot with the antibody directed against LMP2 (Table 4).

By investigating the colorectal cell lines for LMP7 protein (Fig. 4D), we saw results very similar to the mRNA results (Fig. 2B). In 4 independent experiments, the LMP7 Q/Colo320DM homozygous cell line increased the amount of LMP7 protein after stimulation up to 28.1-fold, whereas the induction was dramatically reduced to a maximum of 2.0-fold in the LMP7-K/Q (WEB2) heterozygous cell line. The homozygous LMP7-K/K cell line (SW480) barely produced Lmp7 protein and did not increase the amount after IFN-γ stimulation, which is in line with the minimal increase of HLA class I surface expression upon IFNγ induction.

Discussion

Cancer cells can escape immune recognition by insufficient expression of peptides presented by the MHC because presentation of immunogenic tumor peptides by HLA class I is a prerequisite of a successful antitumor immune responses (3). Efficient expression of peptide–HLA complexes at the cell surface depends on type and quantity of produced and processed peptides. Genetic polymorphisms of immunoproteasome subunits LMP7 and LMP2 and of transporter subunits TAP1 and TAP2 are documented (11, 12, 27). Association studies indicated a participation of the antigen processing machinery in carcinogenesis, for example, in carcinomas of the esophagus (28) and the cervix (29). In this article, we used

Table 3. Combinatorial LMP2/LMP7 genotypes of all CRC patients, colon, and rectum carcinoma patients.

Cancer Res; 71(23) December 1, 2011 Cancer Research
cancer (3, 22, 31–35), and certain HPV types have been identified as main factors in the pathogenesis of cervical and anogenital tissue or microbial peptides for example Helicobacter pylori (17) in the proximal segment or HPV (3) in the distal segment of the large intestine. Therefore, it is conceivable that certain pathogens of the intestine could disturb immunoproteasome formation. Certain HLA alleles and certain HPV types have been identified as main factors in the pathogenesis of cervical and anogenital cancer (3, 22, 31–35), and Helicobacter pylori has been implicated in the pathogenesis of gastric cancer and cancer of the colon (17). We were not able to detect Helicobacter pylori DNA in any of our tumor samples and found HPV in only 5% of the tumors. This does not exclude a possible impact by a former

colorectal carcinomas to identify susceptibility associated alleles of the antigen processing machinery and to elucidate subsequently functional differences of those alleles. It must be stated, that the LMP7 polymorphism in this study is located in the presence of LMP7 and is therefore absent in the mature protein (see Fig. 2C). The polymorphism can therefore not affect the enzymatic activity of LMP7, but can only affect the assembly of the immunoproteasome, either by reducing the level of LMP7 or by interfering with the complex process of assembly, which depends on the prescence.

**Figure 2.** Transcript induction after IFN-γ treatment in colorectal cancer cell lines carrying the LMP7-Q/Q, LMP7-Q/K, and LMP7-K/K genotype, respectively. Reverse transcriptase real-time PCR analyses of cell lines using G6PD as internal standard and primer probe sets for the dedicated LMP7-mRNA transcripts (A) and HLA-B, TAP1, and TAP2 (B, x axis). The results are given in fold-induction (γ axis) compared with the results of untreated cell lines. A, the bold lines represent the mean values for the cell lines with dedicated genotype. Gray colored lines give the results for LMP7-Q/Q carrying cell lines (open circles), black colored lines give the results for LMP7-K/K carrying cell lines (filled circles). The half filled circle represents the heterozygous LMP7-Q/K cell line WEB2. For the LMP7-Q/Q outliers (defined by value above 2 times SD) the fold inductions are given in brackets. Significant differences between LMP7-K/K and LMP7-Q/Q homozygous cell lines were not observed with probes for exon 3 (E3) with a mean of 3.84-fold (±2.86) versus a mean of 10.08-fold (±0.98) and for exon 2 with a mean of 3.49-fold (±2.43) versus an 8.81-fold mean (±0.61; P < 0.05 U test). B, as expected, no significant difference of TAP1 and HLA-B transcript amounts were observed between the LMP7-K/K, LMP7-Q/Q, and LMP7-K/K carrying cell lines after IFN induction. C, schematic of LMP7 gene structure, splice variants, and location of allelic variants. The cartoon depicts the LMP7 gene with its 7 exons (boxes). The exons 1 (light blue) and 2 (red) are used alternatively, resulting in the transcripts LMP7-E1 and LMP7-E2, respectively. Only LMP7-E2 is transcribed into a mature protein. Exon 2 codes the presence of LMP7 that is necessary for the incorporation into the immunoproteasome and is clipped after the assembly of the immunoproteasome. The exons 3 to 7 (dark blue) encode the catalytically active LMP7 subunit.

**Figure 3.** Increased mRNA decay of LMP7-K. To show the difference in LMP7-K and LMP7-Q mRNA decay rates, the LMP7-K/K cell lines, SW948 and Caco-2, and the LMP7-Q/Q cell lines, Colo320DM, were stimulated with IFN-γ prior to the addition of actinomycin D. Using 18S-RNA as an internal reference, actinomycin D chase and quantification of LMP7-mRNA levels were evaluated as described under Materials and Methods. The decay is given in percentage of transcript amount at time point 0 hour (γ axis); the time points are given on the x axis. The mean RNA levels are shown.

**Table 1.** LMP7-K and LMP7-Q allele frequencies among patients and controls. But the biallelic genetic system of the immunoproteasome subunit LMP7 showed a strong association with susceptibility to colorectal cancer. Patients with colorectal carcinoma carried the LMP7-K allele 3 times more often than control individuals (44.2% versus 12.1%), usually together with the LMP7-Q allele (40.2% compared with 12.1% of the controls, P = 3.88 × 10⁻³). Table 1, Fig. 1). The LMP7-Q/Q genotype was underrepresented among patients with colorectal carcinoma (patients 55.8%, controls 87.9%; P = 3.50 × 10⁻¹¹, Table 1). Interestingly, the strength of association between LMP7-K and tumor patients was stronger for patients with tumors in the proximal part of the large intestine (colon) and less strong in the distal part (rectum; Table 1, Fig. 1).

The change of strength in disease associations of the LMP7-K/Q genotype in different tumor locations could reflect different challenges for the LMP7-K allele in processing location-specific tissue or microbial peptides for example Helicobacter pylori (17) in the proximal segment or HPV (3) in the distal segment of the large intestine. In addition, it has been shown that the presence of LMP7 is a possible target for pathogens (30). Therefore, it is conceivable that certain pathogens of the intestine could disturb immunoproteasome formation. Certain HLA alleles and certain HPV types have been identified as main factors in the pathogenesis of cervical and anogenital cancer (3, 22, 31–35), and Helicobacter pylori has been implicated in the pathogenesis of gastric cancer and cancer of the colon (17). We were not able to detect Helicobacter pylori DNA in any of our tumor samples and found HPV in only 5% of the tumors. This does not exclude a possible impact by a former...
inflammatory infection as evidenced for *Chlamydia trachomatis* and subsequent HPV infections in the development of cervical carcinomas (36).

The strong association observed between LMP7-K and colorectal cancer patients prompted us to look for functional consequences of LMP7-K versus LMP7-Q expression. IFN-γ stimulation revealed dramatic differences in the inducibility of LMP7-K and LMP7-Q. The amount of mRNA increased only weakly in LMP7-K–positive cell lines after stimulation with IFN-γ (Fig. 2A). In as much as the HLA class I and TAP subunit RNAs were induced in these cells (Fig. 2B), this is likely to be due to the low LMP7-K expression and probably a consequence of the significantly reduced mRNA stability of LMP7-K (Fig. 3). Chase experiments with actinomycin D indicated that the low LMP7-K levels are likely to be a consequence of a reduced half life (mean $t_1/2 = 7$ minutes) compared with LMP7-Q (mean $t_1/2 = 33$ minutes; Fig. 3). LMP7-K/K cells were also not able to upregulate surface HLA expression after IFN-γ stimulation (Fig. 4).

We predict, that the reduced mRNA stability of LMP7-K will lead to reduced amounts of LMP7 proteins, as shown by Western blot analysis (Table 4 and Fig 4D), and therefore to fewer immunoproteasomes. Because the maturation of immunoproteasomes depends on the incorporation of LMP7, impairment in immunoproteasome assembly or maturation could explain the reduced HLA class I surface expression observed in LMP7-K/K cells after IFN-γ stimulation. This would alter the processing of microbial as well as of tumor-associated proteins and lead to changes in the peptide repertoire presented by HLA class I molecules. It

has to be stated, that although some antigenic peptides are better produced by immunoproteasomes than by regular proteasomes, the opposite is true for other antigenic peptides. It was proposed that deficiency in immunoproteasome expression could diminish the ability of T cells to recognize and destroy tumor cells (37). In a case report, a patient had high numbers of antimelanoma (Melan-A)–specific T cells, but did not destroy the tumor (37). The authors discussed that the "analysis of the proteasome pathway revealed a decreased expression of the subunits of the low molecular weight protein (LMP) 2 and LMP7 as possible explanation for the tumor evasion" (37). Another explanation would be the granyme levels of the T-cell infiltrates (38). Rudimentary information of T cells would lead to defective immune responses and faster chronic inflammation, a known cofactor in carcinogenesis. LMP7 seems to be involved in inflammatory processes because blocking of LMP7 attenuated progression of experimental arthritis in mice (39). Furthermore, the efficiency of the cross-priming pathway, considered a requisition for the induction of HLA class I–restricted immune responses against tumors, might be impaired as well. The exact mechanism by which LMP7 alleles influence susceptibility to CRC needs further clarification.

We have shown that alleles of the immunoproteasome subunit LMP7 show distinct reactions upon IFN-γ stimulation, displaying fundamental differences of RNA transcript levels, RNA stability, and of pMHC surface expression. It should be examined, whether the failing function of the cancer-associated allele LMP7-K could be a target of therapeutic interventions. At present, LMP7-K could be used to screen for indi
duals with the cancer-associated allele, because LMP7-K surpasses all other known risk factors associated with sporadic colorectal cancer (40, 41).
