Running title: Cancer therapy with NK receptor-fusion protein

Key words: Cancer immunotherapy, CD8 T cells, NKG2D, chimeric protein, myeloid suppressor, regulatory T cells.

Abstract word count: 222; Manuscript word count: 4884
Abstract

T cell immunotherapy is a promising strategy to treat cancer but its efficacy, complexity and costs may pose challenges. In this study, we report the results of an investigation of a simple new approach to selectively activate a T cell attack against tumor cells. The immunotherapeutic approach we developed utilizes a bi-functional fusion protein that binds tumor cells through NK activating receptor NKG2D and that recruits and stimulates T cells through an anti-CD3 single chain fragment (scFv-NKG2D). In vitro, this scFv-NKG2D fusion protein engaged both T cells and tumor cells, stimulating T cells to produce IFN-γ; and cytotoxicity against NKG2D ligand-positive tumor cells. In vivo, expression of scFv-NKG2D by NKG2D ligand-positive tumor cells reduced tumor burden and, in some cases, led to tumor-free survival. Administration of scFv-NKG2D in vivo also promoted survival in a murine lymphoma model. Tumor-free mice were resistant to rechallenge with cognate tumor cells, suggesting that a host-specific immunological memory response had been generated. Host adaptive immunity including γδ T cells) was required for scFv-NKG2D-mediated therapeutic efficacy. scFv-NKG2D also inhibited the growth of NKG2D ligand-negative B16F10 tumors, reduced the percentage of myeloid-derived suppressor cells as well as regulatory T cells, and increased the infiltration of T cells, suggesting that scFv-NKG2D may target these immune suppressive cells. Together, these results establish scFv-NKG2D as a promising biologic to induce effective anti-tumor immunity.
Introduction

T cells can play an important role in controlling tumor growth and prolonging survival in cancer patients (1). However, it is difficult to mount and sustain effective tumor-specific T-cell responses due to weak immunogenicity of tumor antigens, clonal deletion of high affinity T cells, low frequency of antigen-specific T cells, down-regulation of MHC molecules, existence of immune suppressor cells and tumor-derived immunosuppressive molecules (2-4). Although adoptive transfer of T cells can partially restore anti-tumor immunity, in vitro generation of large numbers of tumor-specific T cells for treatment still remains a difficult task.

Alternatively, T-cell-mediated anti-tumor immunity can be achieved using bi-specific T cell-engagers, which bind to a surface target antigen on cancer cells and to CD3 on T cells (5). This strategy allows T cells to recognize tumor cells and become activated irrespective of their T-cell receptor specificity and their activation by antigen presenting cells. Recent results from a clinical trial with a CD19/CD3-bispecific antibody showed promise as a cancer treatment (5, 6).

Natural killer (NK) cells attack tumor and virally infected cells in the absence of MHC restriction, utilizing a combination of multiple activating receptors. One of these activating receptors is NKG2D. The ligands for NKG2D receptor include Rae-1, Mult-1 and H60 in mouse; MICA/B and RAET1, also called UL-16 binding proteins (ULBPs), in human, which are preferentially expressed on tumor cells but not on most normal tissues(7-9). NKG2D ligands represent ideal targets for immunotherapeutic approaches because they are selectively over-expressed on many types of tumor cells as well as on tumor-associated suppressor cells (10, 11). Therefore, the NKG2D receptor-NKG2D ligand system provides a relatively specific system for immune cells to recognize tumor cells and the tumor microenvironment. In this study, we describe a novel anti-tumor strategy based on a bi-specific T-cell engager (scFv-NKG2D), in
which a single chain variable fragment (scFv) of anti-CD3ε was fused to the extracellular domain of NKG2D receptor. Our hypothesis was that scFv-NKG2D would bind NKG2D ligand-positive tumor cells via NKG2D and activate T cells via anti-CD3ε scFv portion, leading to elimination of the tumor and induction of host anti-tumor immunity. Because many types of tumor cells (leukemia, lymphoma, colon, breast, prostate, and ovarian cancers, among others) and immune suppressor cells (myeloid-derived suppressor cells and regulatory T cells) express NKG2D ligands (9-11), scFv-NKG2D targeting provides a means to engage T cells against multiple types of tumor cells as well as local tumor immune suppressor cells.
MATERIALS AND METHODS

Mice and cell lines

C57BL/6 (B6, wildtype, wt) were purchased from NCI (Frederick, MD). TCRα−/− mice (B6 background) were obtained from Dr. William R. Green (Dartmouth medical School). Rag1−/− mice (B6 background) were purchased from the Jackson Laboratory (Bar Harbor, ME) and bred in the animal facility of Dartmouth College. Animals used in experiments were between 7 and 12 weeks of age. All experiments were conducted according to protocols approved by Dartmouth College’s Institutional Animal Care and Use Committee. Anti-mouse CD3ε hybridoma 145.2C11 was obtained from ATCC (Manassas, VA). H-2Kb-restricted B3Z T cell hybridoma cells which recognize the OVA257–264 epitope were obtained from Dr. Nilabh Shastri (University of California at Berkley). Upon activation, B3Z cells express the LacZ gene (12). Murine colon cancer MC-38 cells (H-2b) were obtained from Dr. Richard J. Barth (Dartmouth Medical School). Mouse T cell line lymphoma RMA and RMA/RG, ovarian cancer cells ID8 and melanoma B16F10 have been described previously (13-15). Mastocytoma cell line P815/Rae1 was generated by retroviral transduction of P815 cells (H-2d) with a mouse NKG2D ligand Rae1. RMA and B16F10 cells are NKG2D ligand-negative, whereas RMA/RG, P815/Rae1, ID8 and B3Z cells are NKG2D ligand-positive. Packaging cells PT67 (ATCC) and ovarian cancer ID8 cells were grown in Dulbecco's modified Eagle medium (DMEM) with a high glucose concentration (4.5 g/liter) supplemented with 10% heat-inactivated fetal bovine serum (FBS; Hyclone, Logan, Utah), 100 U/ml penicillin, 100 μg/ml streptomycin, 1 mM pyruvate, 10 mM Hepes, 0.1 mM non-essential amino acids and 50 μM 2-mercaptoethanol. All other cell lines were cultured in RPMI plus the same supplements as in DMEM.
**Construction of scFv-NKG2D**

Variable regions of both heavy ($V_H$, aa 1-136) and light chains ($V_L$, without signal peptide, aa 21-128) were PCR amplified using cDNA derived from 145.2C11 hybridoma. Extracellular domain of murine NKG2D was amplified using the full length NKG2D cDNA as template (16). To make anti-CD3ε scFv, $V_H$ and $V_L$ were joined with a 15-amino acid glycine (G)-serine (S) linker (G4S)$_3$ (three repeats of GGGGS). All PCR reactions were performed using a high-fidelity DNA polymerase Phusion™ (New England Biolabs, Ipswich, MA). All oligos were synthesized by either Integrated DNA Technologies (Coralville, IA) or Sigma-Genosys (Woodsland, TX). ScFv-NKG2D was created by joining anti-CD3ε scFv to the extracellular domain of mouse NKG2D (aa 90-232) with a second (G4S)$_3$ linker. A histidine tag (6xHis) was added at the C-terminus to facilitate protein purification. The fusion gene was then cloned into a retroviral vector pFB-neo (Stratagene, Palo Alto, CA). A negative control fusion gene scFv-HuNKG2D was constructed by joining the scFv with the extracellular domain of human NKG2D gene.

**Production of scFv-NKG2D protein**

ScFv-NKG2D proteins were expressed in retroviral vector-stably transduced B16F10 cells according to our previous protocols(16, 17). Briefly, B16F10 cells were retrovirally transduced with vectors that were generated from scFv-NKG2D-stably transfected packaging cell PT67 for 5 rounds. Stable B16F10 cell lines with amplified expression of scFv-NKG2D (either human or mouse version) were selected with G418 (1.5 mg/ml) for 14 days. The resulting stable B16F10 lines (B16F10/scFv-mNKG2D and B16F10/scFv-HuNKG2D) were then cultured in serum-free media (293 SFM II, Invitrogen, Carlsbad, CA). Supernatants were collected every 48 h and were subjected to affinity chromatography using HisTrap™ columns (GE Healthcare Bio-Sciences, Piscataway, NJ) according to the manufacturer’s instructions. Eluted fractions were then
concentrated and desalted using Amicon Ultra columns (30K MWCO, Millipore, Billerica, MA). Purified scFv-NKG2D proteins were resuspended in PBS, filtered (0.22 μm) and stored in -20°C. The integrity of scFv-NKG2D protein was determined by SDS-PAGE, followed by staining with SYPRO® orange (Invitrogen) and visualized using a Typhoon 9400 imager (GE Healthcare). Concentration of scFV-NKG2D was quantitated with ImageJ software (US National Institutes of Health; http://rsb.info.nih.gov/nih-image/Default.html).

Flow cytometry

To determine whether scFv-NKG2D binds to CD3ε, RMA cells were stained with scFv-NKG2D (0.01-1 μg/ml), followed by staining with PE-labeled anti-mouse NKG2D mAb (CX5, eBioscience, San Diego, CA) or isotype control mAb. In a blocking experiment, RMA cells were pre-incubated with anti-CD3ε (145.2C11, eBioscience, 0.01-1 μg/ml) at room temperature for 15 mins prior to staining with scFv-NKG2D. Rae1 expression was determined by flow cytometry using APC labeled pan anti-Rae1 mAb (Clone 186107, R&D systems, Minneapolis, MN). Infiltration of CD4+ and CD8+ T cells, T cell activation (CD69 expression), myeloid-derived suppressor cells (CD11b+F4/80+Gr1+) and regulatory T cells (CD4+Foxp3+) in tumors were determined by flow cytometry after digestion of excised established tumors using cocktails of DNAse and collagenase according to our previous protocol (18). All samples were preincubated with FcR block antibody (anti-mouse CD16/CD32) to reduce nonspecific staining. Cell fluorescence was monitored using an Accuri cytometer (Ann Arbor, MI). Flow cytometry analysis was performed using either Accuri or FlowJo software (Ashland, OR).

Cytokine production by T cells

To determine whether scFv-NKG2D can engage both T cells and tumor cells and lead to T cell activation, spleen cells were stimulated with ConA and IL-2 for 4 days before co-culture with
tumor cells with or without scFv-NKG2D (50 ng/ml) for 24 h. Amounts of IFN-γ in supernatants were analyzed with ELISA. For tumor cells grown in suspension, co-culture with pre-activated murine primary T cells (10^5) was performed in round-bottom 96-well plates at a ratio of 1:1, whereas adherent tumor cells (2.5x10^4) were co-cultured with T cells in flat-bottom plates. Tumor cells were irradiated (120 Gys) before use. Cell-free supernatants were collected after 24 hr. Twenty-four-hour supernatants were assayed for IFN-γ by ELISA using Duoset ELISA kits (R&D systems).

**Cytotoxicity assay**

Lysis of target cells was determined by a 5-hr ^51^Cr release assay as previously described (16, 17).

**BetaRed staining**

The LacZ activity in B3Z cells was determined by using a BetaRed™ β-Galactosidase assay kit (EMD bioscience, San Diego, CA,) according to the manufacturer’s instruction.

**Tumor inoculation**

For the determination of effects of local expression of scFv-NKG2D on MC-38 or B16F10 tumor growth, either WT or scFv-NKG2D-transduced tumor cells (5x10^5) were injected s.c. into the shaved right flank of recipient mice. Tumors were then measured every two days using a caliper, and tumor areas were calculated. Mice were sacrificed when tumor burden became excessive. Animals were regarded as tumor free when no tumor was found four weeks after inoculation. For the rechallenge experiments, mice were inoculated with 10^5 WT MC-38 cells on the shaved left flank. In the systemic lymphoma model, B6 mice were injected with 10^5 of RMA/RG cells via tail veins in 400μl of HBSS. For treatment with recombinant scFv-NKG2D proteins (either mouse or human NKG2D fusion protein), mice were administered i.v. with 5
μg scFv-NKG2D on days 5, 7 and 9 post-tumor inoculations. Mice were monitored closely and sacrificed when moribund signs were observed.

**Statistical analysis**

Differences between groups were analyzed using the student’s $t$ test. Values $p<0.05$ were considered significant. Kaplan-Meier survival curves were plotted and analyzed using Prism software (GraphPad Software, San Diego, CA).
RESULTS

Construction and expression of scFv-NKG2D.

ScFv-NKG2D was made by joining anti-CD3ε scFv to the extracellular domain of NKG2D receptor. The structure of scFv-NKG2D is shown in Fig. 1. Two 15-aa (G4S)₃ linkers were inserted between VH and VL as well as between scFv and NKG2D to allow flexible interactions among scFv-NKG2D, CD3ε and NKG2D ligands. Human NKG2D was also used to make a control fusion protein scFv-huNKG2D since human NKG2D receptor has minimal cross-reactivity with mouse NKG2D ligands. In scFv, the antibody Fc fragment is removed. Therefore, binding of these fusion proteins to FcR-positive cells (such as macrophages, B cells, neutrophils, dendritic cells and endothelial cells via the Fc region) is eliminated, resulting in less non-tumor associated T cell activation. As shown in Fig.1B, purified scFv-NKG2D proteins were monomers at sizes around 50 kD under both native and reducing conditions, which were in line with the expected sizes of 44 kD.

ScFv-NKG2D fusion protein binds to both CD3ε and NKG2D ligands.

To determine whether scFv-NKG2D fusion protein preserves the binding affinity and specificity of the parental anti-CD3ε 145-2C11 antibody, CD3⁺NKG2D⁻ T cell lymphoma RMA cells were stained with scFv-NKG2D (0.01-1 μg/ml), followed by staining with anti-NKG2D-PE (Fig. 2A). As shown in Fig. 2B, scFv-NKG2D binds to CD3ε in a dose-dependent manner. In addition, pre-incubation of RMA cells with 145-2C11 mAb (0.1-10 μg/ml) could block the binding of the scFv-NKG2D fusion protein to RMA cells in a dose-dependent manner, indicating the specific recognition of CD3ε molecule by scFv-NKG2D (Fig. 2C).

To examine whether scFv-NKG2D was capable of binding simultaneously to both T cells via scFv and tumor cells via NKG2D (Fig. 2D), a mouse T hybridoma B3Z was used. B3Z T cells
express both CD3ε and an NKG2D ligand Mult1 (data not shown). We hypothesized that if scFv-NKG2D binds to CD3ε and Mult1 on B3Z cells simultaneously, cross-linking of CD3ε molecule will lead to activation of T cells. Since B3Z cells contain the IL-2 promoter-controlled LacZ gene as a reporter, after activation, B3Z cells will express LacZ (β-galactosidase). The ability of scFv-NKG2D to stimulate Mult1⁺ B3Z cells was evaluated by measurement of the OD₅₇₀nm or OD₅₅₀nm values after addition of a beta-red substrate. As expected, incubation of B3Z cells with scFv-NKG2D, but not with control molecule scFv-HuNKG2D (human), led to cell activation in a dose-dependent manner, indicating that the scFv-NKG2D can engage both T and tumor cells via NKG2D ligands. Based on the data (Fig. 2D), we estimate the ED₅₀ of scFv-NKG2D for activating T cells was about 10 ng/ml.

**ScFv-NKG2D activates primary T cells by producing IFN-γ and exerting cytotoxicity.**

To investigate whether scFv-NKG2D stimulates primary T cells, we examined IFN-γ production and cytotoxicity of T cells against tumor cells in the presence of scFv-NKG2D. ConA and IL-2 (25U/ml) pre-activated T cells were used as effector cells. As shown in Fig. 3 A&B, in the presence of scFv-NKG2D (50 ng/ml), T cells produced significant amounts of IFN-γ after coculture with NKG2D ligand-positive cells (RMA/Rae1, P815/Rae1 and ID8) but not with ligand-negative RMA and B16F10 cells indicating that scFv-NKG2D allows T cells to functionally recognize NKG2D ligand-bearing tumor cells. In contrast, control protein scFv-HuNKG2D does not significantly stimulate T cells to produce IFN-γ in the presence of NKG2D ligand positive tumor cells. These data indicate that anti-CD3ε scFv itself has minimal ability to activate T cells under these conditions. T-cell cytotoxicity in the presence of scFv-NKG2D against various tumor cells was also determined. As shown in Fig. 3C, T cells were able to lyse NKG2D ligand-positive target cells (P815/Rae1, ID8 and MC-38) but not the ligand-negative
cell line B16F10 in vitro in the presence of scFv-NKG2D. Similar to IFN-γ production, no significant killing was observed when control protein scFv-huNKG2D was used. In addition, we also demonstrated that scFv-NKG2D did not affect NK cell-mediated cytotoxicity against tumor cells despite the facts that incubation of high concentration (1 μg/ml) of scFv-NKG2D with tumor cells reduced surface NKG2D ligand expression (Supplemental Fig. 1).

**ScFv-NKG2D suppresses growth of NKG2D ligand-positive tumor cells in vivo and induces a host memory response.**

Having shown that T cells could react against NKG2D ligand-positive tumor cells in vitro after engagement with scFv-NKG2D, we determined the therapeutic potential of scFv-NKG2D in vivo. First, colon cancer MC-38 cells that stably secreted scFv-mNKG2D (supplemental Fig. 2) were tested for growth in vivo after subcutaneous injection. This design represents a localized scenario for scFv-NKG2D treatment that could be produced by exogenous gene transfer. MC-38 cells expressing scFv-human NKG2D fusion protein (scFv-HuNKG2D) were used as negative control. There was no significant difference between wildtype and scFv-NKG2D-expressing MC-38 cells to grow in vitro (data not shown). As shown in Fig. 4A, scFv-mNKG2D expression by MC-38 tumor cells significantly reduced or prevented tumor growth compared to wildtype and scFv-HuNKG2D-expressing MC-38 tumor cells. Fifty nine percent of B6 mice (13 out of 22) receiving MC-38/scFv-mNKG2D tumor cells were tumor-free after 30 days. In a second and more stringent model, lymphoma-bearing mice that had been given NKG2D ligand-positive T cell lymphoma RMA/RG cells i.v. were treated with 3 doses of either recombinant scFv-mNKG2D (5 μg per dose, i.v.) or scFv-HuNKG2D (specificity control). As shown in Fig. 4B, systemic administration of scFv-mNKG2D significantly improved survival of tumor-bearing mice. The median survival increased from 18 days (HBSS) to 31 days (P<0.01); whereas
treatment with control molecule scFv-HuNKG2D only lead to median survival of 23 days. In addition, 39% (7/18) of the scFv-mNKG2D treated lymphoma-bearing mice were tumor-free after 45 days. As for toxicity, the animals treated with scFv-mNKG2D proteins did not show any overt evidence of inflammatory damage (i.e., ruffled hair, hunchback, or diarrhea) suggesting there was no overt toxicity (data not shown).

To determine whether treatment with scFv-NKG2D induced a host memory response against wild-type tumor cells, scFv-NKG2D-treated mice that had remained tumor-free after 45 days were challenged with either wildtype MC-38 (10⁵) or RMA (NKG2D ligand-negative, 10⁴) cells on their left flank. These tumor-free mice were resistant to a subsequent challenge of the same type of tumor cells; whereas all control naïve mice had large tumors after 3 weeks (Fig. 4C &D). This observation indicated that scFv-NKG2D treatment induced hosts to generate specific immunological memory against tumor antigens.

**Host adaptive immunity is involved in scFv-NKG2D-mediated anti-tumor efficacy.**

Since scFv-NKG2D protein uses T cells to target tumor cells, it is expected that the absence of T cells would render scFv-NKG2D treatment ineffective in reducing tumor growth. To test this hypothesis, either wildtype MC-38 or scFv-NKG2D-expressing MC-38 cells (MC-38/scFv-NKG2D) were inoculated (at a dose of 5x10⁵ cells) subcutaneously into B6.RAG1<sup>−/−</sup> mice, which lack T and B lymphocytes. As expected, both wildtype and MC-38/scFv-NKG2D cells grew progressively in B6.RAG1<sup>−/−</sup> mice (Fig.5A). Thus, lymphocytes play an obligate role in scFv-NKG2D-mediated anti-tumor growth *in vivo*.

γδ T cells constitute a major T-cell subset in skin and intestine and can be harnessed for cancer immunotherapy (19). Therefore, scFv-NKG2D may mobilize and activate γδ T cells against subcutaneous tumors, resulting in tumor reduction. The role of γδ T cells was investigated by...
inoculating either WT MC-38 or scFv-mNKG2D-expressing MC-38/scFv-NKG2D cells into TCRα-deficient mice, in which αβ T cells are deficient and γδ T cells remain intact (20). Compared to WT tumors, MC-38 cells that express scFv-NKG2D show markedly slower growth (Fig. 5A). However, no tumor-free mice were obtained. This result suggests that γδ T cells play a role in scFv-NKG2D-mediated therapeutic efficacy against subcutaneous tumors, but αβ T cells are also required for efficient anti-tumor effects.

**Tumor-associated host cells play roles in scFv-NKG2D-mediated anti-tumor efficacy.**

Several studies have shown that some immune cells, such as regulatory T cells (Treg) and myeloid-derived suppressor cells (MDSCs) express NKG2D ligands (10). Nausch et al. demonstrated that Gr-1+CD11b+F4/80+ MDSCs isolated from tumor-bearing mice but not myeloid cells from naïve mice, expressed a NKG2D ligand Rae1. Interestingly, these tumor-associated MDSCs can stimulate NK cells to produce IFN-γ in a manner that is partially dependent on the interaction between NKG2D and its ligands (10). In fact, NKG2D can be used to target Tregs at the tumor site in ovarian cancer (11). To determine whether tumor-associated host cells are involved in scFv-NKG2D-mediated therapeutic efficacy, we tested the effects of local expression of scFv-NKG2D on the growth of B16F10 tumors, which do not express NKG2D ligands in vitro or in vivo (Supplemental Fig. 3). If B16F10 tumor-associated host cells (such as MDSCs and Tregs) are targeted by scFv-NKG2D, it would be expected that B16F10 tumor growth may be reduced by the local expression of scFv-NKG2D. As shown in Fig. 5B, local expression of scFv-NKG2D significantly reduced B16F10 tumor growth, suggesting that scFv-NKG2D may target ligand+ tumor-associated host cells. There was no difference between B16F10 and B16F10/scFv-NKG2D in terms of *in vitro* growth (Supplemental Fig. 4).
To further understand whether Tregs and MDSCs can be targeted, we first checked an NKG2D ligand Rae1 expression on those cells in both MC-38 and B16F10 models. As shown in supplemental Fig. 5C, Rae1 was expressed on tumor (both MC-38 and B16F10)-derived Tregs (CD4⁺Foxp3⁺) and MDSCs (CD11b⁺F4/80⁺Gr1⁺). In contrast, CD4⁺Foxp3⁺ and CD11b⁺F4/80⁺Gr1⁺ cells from naïve B6 spleens did not express Rae1, suggesting that tumor microenvironment plays a role in NKG2D ligand expression. Next, it was tested whether local expression of scFv-NKG2D could alter the ratios of effector CD4⁺/Treg and Gr1⁻/Gr1⁺ (CD11b⁺F4/80⁺) using the B16F10 melanoma model. If tumor-derived Tregs and MDSCs were targeted, one would expect lower percentages of these cells in tumors. As demonstrated in Fig. 6, local expression of scFv-NKG2D by B16F10 cells significantly (P<0.01) reduced the percentage of both Tregs (Fig. 6A) and MDSCs (Fig. 6B) at the tumor site. In addition, Rae-1 expression by those cells was lower in the presence of scFv-NKG2D (Fig. 6C), consistent with the targeting of tumor-derived Tregs and MDSCs by scFv-NKG2D. Overall, these data support the idea that NKG2D can be used to target both tumor cells and their supportive immunosuppressive cells.

**Local expression of scFv-NKG2D leads to increased recruitment of T cells.**

Since local expression of scFv-NKG2D resulted in reduced tumor growth, we hypothesized that more T cells may be recruited to tumor sites and become more activated. To test the hypothesis, WT B16F10 or B16F10/scFv-NKG2D cells (5x10⁵ cells) were injected into the right flanks of B6 mice. The infiltration of T cells (both CD4⁺ and CD8⁺) as well as T cell activation, as demonstrated by expression of an activation marker CD69⁺, were determined by flow cytometry 19 days post-tumor inoculation. As shown in Fig. 7A&C, the percentage of both CD4⁺ and CD8⁺ T cells was significantly increased in the presence of scFv-NKG2D. In addition, T cells
(especially CD8+ T cells) had a significantly increased expression of CD69, which was consistent with an activated status (Fig. 7B &D).
DISCUSSION

Immunotherapy has emerged as a promising method to treat cancers due to the ability to selectively eliminate tumors. Both vaccination and adoptive immune cell transfer have been utilized against cancers (3). Dendritic cell (DC)-based vaccines have been tested in both animal models and clinical trials. However, DCs need to be delicately conditioned with toll-like receptor (TLR agonists) and cytokines to ensure delivery of both primary as well as co-stimulatory signals for T cell stimulation (21). Otherwise, T cells may be induced into a tolerant state. Although DC-based immunotherapy has proven clinically safe and efficient to induce tumor-specific immune responses, only a limited number of objective clinical responses have been reported in cancer patients (22). In the second strategy, adoptive transfer of T cells or allogeneic bone marrow cells can be performed (23). However, the traditional approaches for obtaining large numbers of tumor-specific T cells are difficult. Allogeneic bone marrow transplantation can cause severe acute graft-versus-host disease (GVHD) and response rate is less than 15% (23). Compared to these two strategies, scFV-NKG2D no longer relies on generation of specific T cells or a regular antigen presentation by dendritic cells. ScFv-NKG2D stimulates host T cells in a MHC-independent manner. Therefore scFv-NKG2D is unlikely to be affected by well documented tumor-escape strategies, such as “down-regulation” of MHC expression. Unlike most of other bi-specific molecules in which a specific tumor-targeting scFv has to be made for targeting certain types of tumors, scFv-NKG2D is a pan-tumor targeting reagent since NKG2D ligands are expressed on many types of tumor cells (colon, ovarian, breast, prostate, melanoma, leukemia, and lymphoma, among others). In addition, NKG2D ligands have restricted expression in normal tissues (9), but they are also expressed on immunosuppressive cells within the tumor microenvironment.
In this study, scFv-NKG2D treatment reduced or abrogated the growth of NKG2D ligand-positive tumors, suggesting that scFv-NKG2D in vivo can lead to effective T cell activation and elicit host T cell responses to tumor cells. Possible mechanisms for this may be the small size of scFv-NKG2D (~50 KD) and existence of flexible linkers which allow efficient formation of immunological synapses and reduce a steric barrier imposed by large, abundant glycoproteins like CD43 and CD45 (24). In adult humans, about one-half of the T cells are memory cells based on the expression of a memory marker CD45RO and their ability to respond to allogeneic cells (25). Therefore, these memory T cells may be primed by NKG2D ligand-positive tumor cells in the presence of scFv-NKG2D even without the help of co-stimulatory molecules. Full-length anti-CD3 mAb, even in very small quantities, can induce T cell activation and its associated toxicity in vivo (26). Non-specific T cell activation is primarily due to antibody Fc fragment binding to FcR which leads to CD3 cross-linking, since anti-CD3-induced non-specific T cell activation was significantly reduced using enzymatically produced F(ab’) (26, 27). In scFv-NKG2D, the Fc fragment was removed. Therefore, non-specific T cell activation due to Fc-mediated events and related toxicities are expected to be low.

Immunosuppressive cells within the tumor microenvironment have been shown to be prevent anti-tumor immunity (28, 29). Effective therapies must not only attack the tumor, but they must change the local microenvironment leading to inhibition of tumor growth. Recent studies have shown that myeloid suppressive cells and regulator T cells (Treg) express NKG2D ligands (10, 30). Both cell types make significant contribution in the immunosuppression of tumor microenvironment. The findings that even NKG2D ligand-deficient tumor cells can be affected by scFv-NKG2D treatment suggest that scFv-NKG2D allows T cells to attack host immunosuppressive cells. Nausch et al. showed that adoptive transfer of NK cells reduced
numbers of Gr-1^CD11b^F4/80^ MDSC cells but not the percentages of Gr-1^CD11b^F4/80^ cells in tumor-bearing mice, suggesting that these MDSCs were targeted in vivo by adoptively transferred NK cells (10). Barber et al. showed that NKG2D can be used as a targeting strategy against Tregs within the tumor microenvironment (11). Our results showed that in both MC-38 and B16F10 models, MDSCs and Tregs expressed an NKG2D ligand Rae1, which is consistent with previous findings. Local expression of scFv-NKG2D in tumors significantly reduced the percentage of these immunosuppressive cells, providing more convincing evidence that MDSCs and Tregs can be targeted by scFv-NKG2D.

In TCRα^β^ mice, αβ T cells are lacking, whereas γδ T cells remain normal (20). As shown in Fig. 7, scFv-NKG2D expression by MC-38 cells also reduced tumor growth in TCRα^β^ mice, suggesting that host γδ T cells can be redirected against NKG2D ligand-positive tumors by scFv-NKG2D. γδ T cells are abundant in skin and mucosa tissues (31). Many studies have suggested that γδ T cells are important components in anti-tumor immunity (32, 33). Therefore in this model, γδ T cells may play a significant role in scFv-NKG2D-mediated early anti-tumor responses.

Since NKT cells also express CD3, it is possible that scFv-NKG2D may engage NKT cells to tumor cells, leading to anti-tumor responses. It has been shown that administration of α-galactosylceramide (αGalCer, an agonist of NKT cells), αGalCer-loaded DCs, or αGalCer-loaded soluble CD1d molecule (αGalCer/sCD1d) could induce significant IFN-γ—producing NKT responses and protect against the development of metastases with B16 melanoma after (34, 35). However, success of α-GalCer treatment in humans has been limited. The partial reason may be that in humans, there exist anti-alpha-linked sugar natural antibodies that do not exist in the mouse (36, 37). Lung and liver contain abundant NKT cells, which may play an important
role in keeping tumor metastasis in check (34, 35)(38). Expression of membrane-bound anti-
CD3 scFv and CD86 on B16 melanoma cells has been shown to suppress tumor growth in vivo
and protect mice from B16 rechallenge. In the subcutaneous B16 model, NKT cells have been
shown to play a critical role in in vivo antitumor activity(39). Therefore, it is possible that scFv-
NKG2D may also engage both NKT and tumor cells, resulting in vivo anti-tumor activity.

T-cell infiltration into tumors (especially CD8\(^+\) T cells) is often correlated with improved
survival (40-42). Recent studies have shown that tumor-specific CD4\(^+\) T cells could also
differentiate in vivo into cytotoxic T cells and induce regression of established melanoma (43,
44). The results that local expression of scFv-NKG2D increased recruitment of T cells and
reduced tumor growth are consistent with these findings. The possible mechanisms for enhanced
T cell-infiltration after scFv-NKG2D treatment may be that scFv-NKG2D engages NKG2D
ligand-positive cells in tumors and resident and/or newly-arrived T cells, resulting in T cell
activation and production of IFN-\(\gamma\) leading to IFN-\(\gamma\)-inducible chemokines such as CXCL9 and
CXCL10 (the ligands for CXCR3), as well as CCL2 (the ligand for CCR2) and CCL11 (the
ligand for CCR2 and CCR5) (44). These chemokines may attract more T cells to tumor sites and
help eliminate tumors.

Regulation of NKG2D ligand expression can occur on multiple levels (transcriptional, post-
transcriptional and post-translational levels)(9). DNA pathways initiated by ATM (ataxia
telangiectasia, mutated) or ATR (ATM- and Rad3-related) protein kinases have been shown to
play important roles in up-regulation of NKG2D ligands (45). Many anti-cancer drugs can also
up-regulate NKG2D ligands (46), which not only potentially enhances the host NK cell anti-
tumor activity but also suggests possible synergistic effects of these drugs with scFv-NKG2D
treatment.
In view of the wide expression of NKG2D ligands on many human cancers as well as Treg and myeloid-derived suppressor cells, the strategy described here has a promising potential to treat many human cancers using direct and indirect mechanisms. The ability of scFv-NKG2D to induce long-term immunological memory may be beneficial to cancer patients with minimal residual disease. Collectively, our findings suggest that scFv-NKG2D represents a promising alternative to elicit host immunity for effective immunotherapy against cancer.
ACKNOWLEDGEMENTS

This study was supported in part by grants from the Hitchcock Foundation (250-4032, TZ) at Dartmouth Medical School, the Department of Microbiology and Immunology and Norris Cotton Cancer Center (CLS); National Institutes of Health (CA130911, CLS; T32AR007576, TZ). We thank Dr. William Green (Dartmouth Medical School) for providing TCRα–/– mice, the NCI Biological Resource Branch for providing recombinant human IL-2 and the staff of the Animal Resources Center for assistance with animal care.

CONFLICT OF INTEREST

Figure legends

**Fig.1 Structure of scFv-NKG2D.** (A) Anti-CD3ε V_h and V_l are linked with a G4S linker (L_1) and fused to the extracellular domain (Ex) of NKG2D receptor with the second G4S linker (L_2) in between. For the convenience of protein purification, a histidine tag (6 repeats of histidine) was added at the C-termini. (B) scFv-NKG2D proteins express as monomers. Transiently transfected 293T cells that were cultured in serum-free media (Invitrogen) were used to express scFv–NKG2D fusion proteins. Both human (Hu, -ve ctrl) and mouse extracellular NKG2D (Ms) portions were fused to anti-mouse CD3ε scFv. Recombinant proteins were purified through nickel columns. The sizes and purity of protein samples were checked by SDS-PAGE either in native (without β-ME) or reducing conditions (with β-ME). The expressed scFv-NKG2Ds showed sizes around 50 kD, which are similar to expected 44 kD.

**Fig. 2 scFv-NKG2D can engage both T cells and tumor cells.** (A) Schematic demonstration of binding assay of scFv-NKG2D to T cells. A T cell lymphoma cell line RMA (10^5, CD3^+ NKG2D^-), which does not express ligands for NKG2D, was stained with scFV-NKG2D (0.01-1 μg/ml) followed by staining with anti-NKG2D-PE. Samples were analyzed with an Accuri C6 flow cytometer. (B) Surface levels of NKG2D on RMA cells after staining with scFv-NKG2D are shown. (C) Anti-CD3 mAb can competitively block the binding of scFv-NKG2D to CD3 molecule in a dose-dependent manner. To confirm that scFv-NKG2D binds to CD3 molecule, RMA cells were pre-incubated with anti-CD3 mAb (0.1-10 μg/ml) prior to staining with scFv-NKG2D. (D) ScFv-NKG2D can activate T cells after cross-linking both CD3 and NKG2D ligands. CD3^+ and NKG2D ligand Mult1^+ T cell hybridoma B3Z cells (10^6/ml) were cultured in the presence of scFV-NKG2D (0.01-1 μg/ml) for 24 h. T cell activation (β-galactosidase activity) was analyzed using a BetaRed analysis as described in Methods and Materials. Human NKG2D-scFv fusion protein (scFv-HuNKG2D) was used as a negative control since human NKG2D receptor does not cross-react with mouse NKG2D ligands.
Fig. 3 T cells respond to NKG2D ligand positive cells by producing IFN-γ and exerting cytotoxicity in the presence of scFv-NKG2D. Bulk spleen cells were stimulated with ConA (1μg/ml) and IL-2 (25 U/ml) before co-culture with irradiated tumor cells for 24 h. Both suspension (A) (10⁵) and adherent tumor cells (B) (2.5x10⁴) were co-cultured with ConA-stimulated spleen cells (10⁵) in 96 well plates. Fusion protein scFv-huNKG2D (in which mouse NKG2D was replaced with the extracellular domain of human NKG2D) is used as negative controls. The final concentrations of scFv-NKG2D are 50 ng/ml. IFN-γ amounts in the supernatants were analyzed with ELISA. Results are shown in mean + SD. These data show that the expression of NKG2D ligands on tumor cells is required for induction of IFN-γ production. *: P<0.01 (scFv-mNKG2D vs ctrl). (C) ConA-stimulated T cells were co-cultured with NKG2D ligand-positive P815/Rae1 (mastocytoma), ID8 (ovarian cancer) and MC-38 (colon cancer) cells and –negative B16F10 (melanoma) at E:T ratios of 1:1 to 25:1 in the presence of scFv-mNKG2D (solid symbols) or control scFv-HuNKG2D (open symbols) of for 5h. The specific lysis was determined by Cr⁵¹-assay. The scFv-NKG2D proteins were added at concentrations of 10 and 100ng/ml. Results are shown in mean + SD of triplicates.

Fig. 4 scFv-NKG2D treatment reduces the growth NKG2D ligand-positive tumors in vivo and induces memory responses. (A) Mouse colon cancer MC-38 cells were genetically modified with a retroviral vector containing either scFv-mNKG2D (☐, n=22) or control molecule scFv-HuNKG2D (▲, n=12) and then injected s.c. (5x10⁵) into right flanks of B6 mice on day 0. Only 9 of 22 mice developed tumors, whereas in HBSS-treated groups (■, n=19) in which wt MC-38 cells were given, all 19 mice developed tumors. The tumor areas are pooled data from four independent experiments. (B) Intravenous administration of scFv-NKG2D promotes survival in a systemic lymphoma model. Treatment of RMA/RG (10⁵, i.v., day 0) tumor-bearing mice with 3 doses of scFv-mNKG2D (Ø, 5μg, i.v. n=19) on days 5, 7 and 9 significantly enhanced survival compared to HBSS (■, n=19) or control molecule scFv-HuNKG2D (n=8). Data is presented in Kaplan-Meier survival curves. *: p<0.002. (C) Tumor free mice (○) in the MC-38/scFv-NKG2D group (shown in panel A) and age-matched naïve mice (■) were re-
challenged with wild type MC-38 cells ($10^5$) s.c. into the left flanks. **(D)** Tumor free mice (○) in the scFv-NKG2D-treated RMA lymphoma model (shown in panel B) and age-matched naïve mice (●) were re-challenged with wild type RMA cells ($10^4$) s.c. into the left flanks. The tumor areas are represented as Mean + SEM. The error bars represent SEM.

**Fig. 5 Host adaptive immune cells are involved in scFv-NKG2D-mediated tumor rejection and local expression of scFv-NKG2D also reduces NKG2D ligand-negative tumor growth.** (A) Either wt (circle) or scFv-NKG2D-expressing (square) MC-38 cells were injected s.c. ($5\times10^5$) into right flanks of Rag1$^{-/-}$ (unfilled) or TCRαβ$^{-/-}$ (filled) mice on day 0. The error bars represent SEM of three pooled independent experiments. Local expression of scFv-NKG2D significantly (P<0.05 at days 5-19) suppressed the MC-38 tumor growth in TCRαβ$^{-/-}$ but not Rag1$^{-/-}$ mice. (B) Either WT (●) (n=10) or scFv-NKG2D-expressing (■) (n=17) B16F10 cells were injected s.c. ($5\times10^5$) into right flanks of B6 mice on day 0. The tumor areas are represented as Mean + SEM. The error bars represent SEM. Local expression of scFv-NKG2D significantly (P<0.01, at days 5-17) suppressed B16F10 tumor growth.

**Fig. 6 Local expression of scFv-NKG2D in tumors reduces the percentages of Tregs and MDSCs.** The percentages of Tregs (CD4$^+$Foxp3$^+$, A) and MDSCs (CD11b$^+$F4/80$^+$Gr1$^+$ B) in either B16F10 or B16F10/scFv-NKG2D tumors were determined by flow cytometry on excised tumor tissues 15 days post-inoculation. Both representative expression profiles (left panel) and individual values (right panel) are shown. Results are pooled data from two independent experiments. *: p<0.01. (C) Rae1 expression by MDSCs and Tregs is reduced in the presence of scFv-NKG2D. Isotype control: black line; Anti-rae1-APC: grey line.

**Fig. 7 scFv-NKG2D treatment significantly increases T cell infiltration in a B16F10 melanoma model.** Infiltration of CD4$^+$ (A) and CD8$^+$ (C) T cells was analyzed by flow cytometry on excised B16F10 tumor tissues 19 days post-inoculation. Results shown are pooled data from two independent experiments.
and are demonstrated as fold-increase, in which the average % in the WT B16F10-injected group was designated as 1. *: \( p<0.01 \). CD69 expression on CD4\(^+\) (B) and CD8\(^+\) (D) T cells was also analyzed.
