Abstract

Intrinsic resistance to agents targeting phosphoinositide 3-kinase (PI3K)/AKT pathway is one of the major challenges in cancer treatment with such agents. The objective of this study is to identify the genes or pathways that can be targeted to overcome the resistance of non–small cell lung carcinoma (NSCLC) to the AKT inhibitor MK2206, which is currently being evaluated in phase I and II clinical trials. Using a genome-wide siRNA library screening and biologic characterization, we identified that inhibition of thioredoxin reductase-1 (TXNRD1), one of the key antioxidant enzymes, with siRNAs or its inhibitor, aurano, sensitized NSCLC cells to MK2206 treatment in vitro and in vivo. We found that simultaneous inhibition of TXNRD1 and AKT pathways induced robust reactive oxygen species production, which was involved in c-jun-NH2-kinase (JNK; MAPK8) activation and cell apoptosis. Furthermore, we found that the synthetic lethality interaction between the TXNRD1 and AKT pathways occurred through the KEAP1/NRF2 cellular antioxidant pathway. Finally, we found that synthetic lethality induced by TXNRD1 and AKT inhibitors relied on wild-type KEAP1 function. Our study indicates that targeting the interaction between AKT and TXNRD1 antioxidant pathways with MK2206 and aurano, a U.S. Food and Drug Administration-approved drug, is a rational strategy to treat lung cancer and that KEAP1 mutation status may offer a predictive biomarker for such combination approaches. Cancer Res; 73(17); 1–12. ©2013 AACR.

Introduction

Previous studies have established the critical role of the phosphoinositide 3-kinase (PI3K)/AKT pathway in cancer cell growth and survival; therefore, strategies that target this pathway have been developed and tested for cancer treatment, including lung cancer (1). MK2206 (Merck, Inc.), a small-molecule inhibitor that targets the AKT signaling pathway, is currently being tested in phase I and II clinical trials and has shown promising results in terms of tumor shrinkage, disease stabilization, and patient tolerability in patients with advanced solid tumor (2). We previously reported that a large subset of human non–small cell lung carcinoma (NSCLC) cells do not respond to MK2206 (3). We and others have also reported that combination with other agents, such as AZD6244 (an inhibitor of mitogen-activated protein kinase kinase) and erlotinib [an EGF receptor (EGFR) inhibitor], sensitized some lung cancer cells to MK2206 (3, 4). Those findings indicate that identification and inhibition of additional targets are needed to improve the efficacy of targeted therapeutic agents, such as MK2206.

Thioredoxin reductase and thioredoxin (TXNRD1/TXN) is one of the major thiol-dependent electron donor systems in cells; it plays a critical role in regulating the cellular redox environment and in a wide range of cellular activities, such as maintenance of viability and proliferation (5). Preclinical studies indicated that aurano, an orally active gold compound and a TXNRD1 inhibitor, induced apoptosis in cancer cells and enhanced the antitumor activities of chemotherapeutic agents (6–10). It is currently being tested in a phase II clinical trial for treatment of chronic lymphocytic leukemia (11), and was recently repurposed as an orphan drug for human amebiasis treatment (12). Other TXNRD1/TXN inhibitors, such as PG12, have also been tested clinically in solid tumors (13, 14). Keck-like ECH-associated protein (KEAP1) and nuclear factor-erythroid-derived-related factor 2 (NRF2) pathways is another major cellular antioxidant pathways. Under normal conditions, KEAP1 binds to NRF2 and promotes degradation by cullin3 (Cul3)-based E3 ligase system (15). Activated NRF2 due to oxidative stress can stimulate multiple antioxidant molecules by binding to antioxidant response elements (ARE; refs. 16, 17). Loss-of-function mutations of KEAP1 have been reported in many cancer types including NSCLC with frequency of about 19% (18–20). KEAP1 mutations cause constitutive activation of...
NRF2, which is associated with cancer progression, treatment resistance, and poor patient survival (21–23). Genome-wide siRNA library screening has been used to identify targets or networks that can be targeted for cancer therapy. siRNA library screening has also been used to identify synthetic lethality loci with specific drugs (24–27). Using genome-wide siRNA library screening and biochemical and biologic methods, we found that inhibition TXNRD1 with siRNAs or inhibitor, auranoxin sensitized lung cancer cells to MK2206 in vitro and in vivo. Our study indicates that auranoxin, a TXNRD1 inhibitor and clinically proven drug that has been used to treat rheumatoid arthritis for 25 years, could be repurposed for lung cancer therapy in combination with MK2206.

Materials and Methods

Cell lines

Human lung cancer cell lines HCC193, H1993, H460, H1299, H2126, H292, H1648, H1838, H1395, H23, H358, H1703, H1666, and A549 were from the Hamon Center for Therapeutic Oncology Research at The University of Texas Southwestern Medical Center (Dallas, TX). Cell lines were maintained in high-glucose RPMI-1640 supplemented with 5% FBS and cultured at 37°C in a humidified atmosphere containing 5% CO2 and 95% air. Cell lines have been authenticated regularly with short-tandem repeat (STR) fingerprinting method.

siRNA library screening

We used the NSCLC cell line HCC193 for genome-wide siRNA screening, because it has a high level of p-AKT and the IC50 for MK2206 is 10 μmol/L (3). The screening concentration of MK2206 is 1 μmol/L, a dose that can sufficiently inhibit phosphorylated AKT (p-AKT) in vitro and in vivo (2, 3). The screening was conducted using a Dharmacon siRNA siGENOME (Dharmacon) library containing 84,508 siRNAs with four unique siRNA duplexes that target each of 21,127 unique human genes. On day 1, 2,000 cells were reverse transfected with 0.07 μL DharmaFECT 4 in a 384-well plate, to a final concentration of 40 nmol/L siRNA per well. MK2206 was added on day 3 at a 1 μmol/L final concentration. Cell growth was analyzed on day 5 using the CellTiter Blue method (Promega). Raw data were log2 transformed. Data were normalized using 16 negative controls in each plate. The t statistics were conducted to compare the significant differences between the values of siRNA transfection and the negative control and siRNA transfection plus MK2206 treatment. P values were obtained using computed t statistics. β-Uniform mixture methods were used to account for multiple tests and estimate the false discovery rate (FDR).

Proliferation assay

The drug treatment protocol was reported in our previous publications (3, 28). In brief, 2,000 cells was plated in 96-well plates and treated with the indicated doses of auranoxin (0–0.5 μmol/L), MK2206 (0–2.5 μmol/L), or both for 72 hours. A sulforhodamine B assay (SRB) was conducted to determine cell viability. IC50 values of auranoxin and MK2206 in each cell line were calculated using Curve Expert 1.3 software and plotted in dose–response curves. Chou–Talalay method was used to calculate the two-drug combination index (CI) using CalcuSyn software (Biosoft; CI, 0.2–0.9, synergism; CI < 0.2, strong synergism; ref. 29).

Western blot analysis

Whole-cell lysates were collected using radioimmunoprecipitation assay (RIPA) reagent. Western blot analysis was conducted with 40 μg of total cell proteins and antibodies against phosphorylated-c-Jun-NH2-kinase (p-JNK), JNK, PARP, p-AKT, AKT (Cell Signaling Technology), KEAP1, NRF2 (Santa Cruz Biotechnology), and TXNRD1 (Abcam).

Gene knockdown and overexpression

Cells were transfected in a 96- or 6-well plate with siRNAs (40 nmol/L) using DharmaFECT 4, and 48 hours posttransfection, cells were treated with dimethyl sulfoxide (DMSO) or MK2206 for additional 72 hours. For stable gene knockdown of KEAP1, short hairpin RNAs (shRNA) in lentivirus plasmids were purchased from Thermo Fisher Scientific, and lentiviruses were packaged using a kit from System Biosciences. Cells were infected with lentiviruses containing specific shRNAs, followed by selection with puromycin (1 μg/mL) for 4 weeks. For overexpression of dominant-negative AKT (AKT-DN) or wild-type KEAP1 (Dsred-KEAP1), plasmids of interest were transfection into HCC193, H1993, and H460 cells, respectively, with Lipofectamine 2000 followed by selection with G418 (500 μg/mL) for 4 weeks.

Measuring reactive oxygen species production

The reactive oxygen species (ROS) measurement method was described in our previous publication (30). In brief, cells (1 × 106/mL) were incubated in Hank’s Balanced Saline Solution containing 50 mmol/L 2,7′-dichlorofluorescein-diacetate (DCFHDA) for 30 minutes. The cell population fluorescence is proportional to the levels of intracellular ROS generated and was measured using fluorescence-activated cell sorting (FACS; Becton Dickinson) at 588 nm emission.

Real-time PCR

The NRF2 downstream molecules glutamate–cysteine ligase catalytic (GCLC) subunit was analyzed using real-time PCR, as described previously (28). The primers for GCLC are forward, 5′-ctgttggaggaagacgtat-g and reverse, 5′-tccacacacgttgctt3′. Primers for glyceralddehyde-3-phosphate dehydrogenase (GAPDH) are, forward, 5′-atccatcactcacccagc-3′ and reverse, 5′-tagtctctccagatc-3′.

Glutathione assay

Glutathione (GSH) levels were tested using the GSH Assay Kit (Sigma). After the indicated treatments, GSH levels were determined using the GSH-reductase recycling assay with 5,5'-dithiobis-(2-nitrobenzoic acid; DNTB) as substrate in microtiter plates, following the manufacturer’s instructions.

TXNRD1 activity assay

Cells (0.5 × 106) were washed with PBS and extracted with CellLytic M. The lysates were centrifuged at 10,000 × g for 10
minutes, and supernatants were used as the enzyme sample. Tumor tissues (from mice) were extracted with four volumes of 0.25 × assay buffer containing protease inhibitor cocktail using a Potter-Evthjem homogenizer. The samples were centrifuged for 15 minutes at 10,000 × g. TXNRD1 activity was measured with a TXNRD1 activity assay kit (Sigma) using DNTB as a substrate.

**Animal experiments**

Animal experiments were carried out according to the approved protocol (10-11-11531) by The University of Texas MD Anderson Cancer Center (Houston, TX) Institutional Review Board and in accordance with the Guidelines for the Care and Use of Laboratory Animals published by the NIH (Bethesda, MD). A total of 2 × 10⁶ H1993 cells were inoculated subcutaneously into the right dorsal flanks of nude mice. Treatment started when tumors reached a mean volume of approximately 40 mm³. Animals bearing xenograft tumors derived from the H1993 cell line were randomly assigned to four treatment groups, with 5 mice in each group: (i) MK2206 only (25 mg/kg; by oral), (ii) auranofin only (5 mg/kg; by intraperitoneal), (iii) MK2206 (25 mg/kg) and auranofin (5 mg/kg), and (iv) solvent only (control). Animals were treated daily, and tumor volumes were measured blindly every 3 days. The tumor volumes were calculated using the formula length × width² × 0.52. Mice were euthanized when their tumor volume was larger than 2,000 mm³. Mean tumor growth was analyzed using the Kruskal–Wallis test for overall significance among different treatment groups and Mann–Whitney U test for significance between two treatment groups (two-tailed). Kaplan–Meier method was used to analyze the animal survival.

**Examination of NRF2 subcellular localization**

Immunofluorescence staining was conducted to determine the subcellular localization of NRF2 in H1993 cells, before and after treatment as described previously (31). NRF2 subcellular localization was also examined with enhanced GFP (EGFP) fusion protein (32). Images were obtained under a Carl Zeiss Deconvolution AxioVision 4 microscope (Carl Zeiss). Nuclear and cytoplasmic fractions were prepared with hypotonic lysis buffer (20 mmol/L Tris pH 7.5, 5 mmol/L MgCl₂, 5 mmol/L CaCl₂, 1 mmol/L dithiothreitol (DTT), 1 mmol/L EDTA, and protease inhibitor cocktail). Cells were passed through 27-gauge needle on ice for 30 times followed by centrifugation at 250 × g for 5 minutes at 4 °C. The supernatant was used as cytoplasmic fraction. The nuclear pellet was thoroughly washed in PBS and nuclear protein was extracted with RIPA.

**Luciferase reporter assay**

Cells (2 × 10⁵) were transfected with ARE-Luc plasmid (provided by Dr. Donna Zhang, Arizona University, Tucson, AZ) and a Renilla-luciferase control plasmid in a 12-well plate using Lipofectamine 2000. Forty-eight hours after transfection, cells were treated with DMSO or MK2206 (1 μmol/L) for 1, 3, 6, or 24 hours. Cells were then collected for luciferase activity assay. Luciferase activity was normalized using a Renilla-luciferase control.

**Statistical analysis**

The t statistics were used to determine the significant differences between the survival values of cells treated with negative control siRNA, targeted siRNA, and targeted siRNA plus MK2206. P values were obtained using computed t statistics. β-Uniform mixture methods were used to account for multiple tests and estimate the FDR. The correlation between KEAP1 mutation and sensitivity to MK2206 and auranofin was determined using the Fisher exact test with two-sided P values at 95% confidence interval. Online Ingenuity Pathway Analysis software was used to conduct a signaling pathway analysis. The significance of the in vitro cell proliferation between and within different treatment groups were determined using Student t test (two-tailed). The significance of the in vivo animal study was determined using the Kruskal–Wallis test for overall significance among different treatment groups and Mann–Whitney U test for significance between two treatment groups (two-tailed). Kaplan–Meier method was used to analyze the animal survival.

**Results**

**Synthetic lethality screening identified MK2206 synthetic lethal hits**

To identify gene candidates that could be targeted to overcome the intrinsic resistance to MK2206 in NSCLC cells, genome-wide siRNA screening was conducted with the Dharmacon siRNA siGENOME library in the NSCLC cell line HCC193. The FDR of 0.1 was used as the cutoff to define the significant hits. Using a P value of 0.007542048 and at least 50% of growth inhibition as the cutoff, we identified 156 hits. We analyzed the significant hits using Ingenuity Pathway Analysis software and found that targets in the NF-κB, autophagy, and cellular redox regulation pathways were synthetically lethal with MK2206 (Fig. 1A and Supplementary Table S1). Using cell proliferation assay and siRNA knockdown, we further validated the top 10 hits, including TXNRD1, CFLAR, ATP5J, SLC9A10, and CLN10. The results showed that knockdown of TXNRD1, CFLAR, SLC9A10, AHCYL1, and CLN10 sensitized both HCC193 and H1993 cells to 1 μmol/L MK2206 (Fig. 1B and C).

**TXNRD1 knockdown sensitized cells to MK2206 treatment by inducing cell apoptosis**

To determine whether TXNRD1 expression levels correlate with the sensitivity to MK2206, we examined the TXNRD1 and P-AKT expression in 4 MK2206-sensitive and 10 MK2206-resistant NSCLC cell lines based on our previous published data (3). We found that the expression levels of TXNRD1 are low in all 4 MK2206-sensitive cell lines, whereas the expressions of TXNRD1 are significantly higher in 7 of 10 resistant cell lines (P<0.01), and there is a correlation of TXNRD1 levels with MK2206 resistance (r = 0.66; Fig. 2A). Knockdown of TXNRD1 with three different siRNAs significantly sensitized the HCC193 and H1993 cells (Fig. 2B and C). Cell apoptosis analysis by flow cytometry revealed that TXNRD1 knockdown combined with MK2206 induced 10% to 30% apoptosis in HCC193 and H1993 cells within 48 hours treatment, whereas no apoptosis was induced in the cells treated with MK2206 or siRNA only.
PARP cleavage, an apoptosis marker, was also observed in HCC193 and H1993 cells treated with TXNRD1 siRNA and MK2206 (Fig. 2E). Those results indicate that TXNRD1 knockdown sensitizes NSCLC cells to AKT inhibition by inducing cell apoptosis.

**TXNRD1 inhibition with auranoﬁn sensitized cells to MK2206 treatment in vitro and in vivo**

To develop a treatment strategy that would be useful clinically, we tested the combination of MK2206 and auranoﬁn, a TXNRD1 inhibitor that is used for rheumatoid arthritis treatment. Inhibition of TXNRD1 by different doses of auranoﬁn was ﬁrst conﬁrmed in HCC193 cells. Approximately, 80% of TXNRD1 activity was inhibited by 0.1 μmol/L auranoﬁn (Fig. 3A), which is consistent with a previous report (33). At 0.1 μmol/L, auranoﬁn did not affect the viability of HCC193 and H1993 cells as was shown in Fig. 3B. We used a dose of 0.1 μmol/L, which can inhibit TXNRD1 activity but not the cell proliferation for the combination with MK2206. Combination of MK2206 (1 or 3 μmol/L) and 0.1 μmol/L auranoﬁn induced signiﬁcant growth inhibition in HCC193 and H1993 cells, P < 0.01 (Fig. 3C). Liquid colonogenic assay further conﬁrmed that combination of 0.1 μmol/L auranoﬁn and MK2206 signiﬁcantly reduced the colony formation in HCC193 and H1993 cells more than 80% compared with vehicle or each single treatment alone (P < 0.01; Fig. 3D and E).

To determine the synthetic lethality induced by MK2206 and auranoﬁn in vivo, xenograft tumors were established with H1993 cells. Single-drug treatment with MK2206 or auranoﬁn had no effect on tumor growth, but the combination signiﬁcantly inhibited tumor growth by 85% in reduction of tumor volumes compared with each drug alone and 90% compared with vehicle treatment (P = 0.009 in all three comparisons). Tumor growth inhibition by auranoﬁn (AUR) or MK2206 (MK) alone was signiﬁcant as compared with vehicle only at a late time point (day 28; AUR vs. vehicle, P = 0.023; MK vs. vehicle, P = 0.047), but the tumor volume reduction was very minimal (~5%; Fig. 3F). This combination also signiﬁcantly prolonged animal survival (median, 76 days) compared with vehicle (median, 31 days) or single-drug treatment (median, 34 days for both single treatments; P < 0.001; Fig. 3G). Signiﬁcant inhibition of TXNRD1 by auranoﬁn and auranoﬁn and MK2206 combination treatment was conﬁrmed in animal tumor tissues (Fig. 3H). Immunohistochemical staining indicated that p-AKT was inhibited in the tumor tissue treated with MK2206 or the combination (Fig. 3I). These results indicate that the combination of MK2206 and auranoﬁn induces synthetic lethality in vivo.
Combination of auranoﬁn and MK2206 induced ROS production, which mediated cell apoptosis

Because TXNRD1/TXN is one of the major cellular redox regulatory systems that regulate cellular ROS, we hypothesized that combination of auranoﬁn and MK2206 may disrupt the cellular ROS balance. Indeed, we found that MK2206 alone induced ROS production in HCC193 and H1993 cells by approximately 2-fold (Fig. 4A). The combination of auranoﬁn and MK2206 induced robust ROS production by 5-fold \((P < 0.05; \text{Fig. } 4B)\). To determine whether ROS induction is essential for cell apoptosis induced by MK2206 and auranoﬁn, we treated cells with the ROS blocker nordihydroguaiaretic acid (NDGA; 20 \(\mu\)mol/L). NDGA blocked the ROS production in HCC193 and H1993 cells induced by the combination (Fig. 4C), and reversed cell growth inhibition in both HCC193 and H1993 cells (Fig. 4D). High level of ROS can activate JNK pathway, which mediated cell apoptosis (34). Indeed, we observed that combination of MK2206 and auranoﬁn induced activation and PARP cleavage in H1993 and HCC193 cells (Fig. 4E). In addition, JNK activation and PARP cleavage were blocked by ROS inhibitor NDGA (Fig. 4F). Those results indicated that combination of MK2206 and auranoﬁn induced ROS production, which mediated the cell apoptosis.

Synthetic lethality induced by auranoﬁn and MK2206 is through the KEAP1/NRF2 pathway

In addition to TXNRD1, KEAP1/NRF2 is another major cellular antioxidant system. Activated NRF2 translocates to the nucleus and stimulates gene expression, such as
GCLC and NAD(P)H dehydrogenase, quinone1 (NQO1), which mediate cellular antioxidant responses (35–37). To determine whether AKT inhibition–induced ROS production was due to NRF2 inhibition, subcellular localization of NRF2 was examined using immunofluorescence staining. The results showed NRF2 was excluded from the nuclei.

Figure 3. MK2206 and auranofin inhibited cancer cell growth in vitro and in vivo. A, inhibition of TXNRD1 activity by auranofin. B, dose responses of HCC193 and H1993 cells to auranofin. C, auranofin sensitized the HCC193 (left) and H1993 (right) cells to MK2206. D, combination of auranofin and MK2206 inhibited colony formation of HCC193 (left) and H1993 (right) cells. Cells (2,000) were plated in 60-mm dishes and treated with DMSO or 0.1 μmol/L auranofin and different doses of MK2206 as indicated for 7 days. Cell colonies were stained with crystal violet and counted. E, relative colony formation was calculated by normalization with control (DMSO) treatment as 100%. Values are the mean ± SD of 3 assays; *, *P < 0.01. F, combination of auranofin and MK2206 inhibited tumor growth in vivo. Values are the mean ± SD, n = 5. AUR-MK versus vehicle: *P = 0.009; AUR-MK versus AUR: *P = 0.009; AUR-MK versus MK: *P = 0.009. G, combination of auranofin and MK2206 prolonged animal survival compared with vehicle, auranofin, or MK2206 alone, *P < 0.001. H, auranofin inhibited TXNRD1 activity in vivo. Fresh tumor samples were obtained after 7 days of treatment, and tumor tissues were minced and assayed for TXNRD1 activity. I, inhibition of p-AKT in vivo; formalin-fixed, paraffin-embedded tissue sections of animal tumor tissue specimens were used for immunostaining with antibodies against p-AKT (Y473).
in the H1993 cells treated with 1 μmol/L MK2206 (Fig. 5A). Luciferase reporter assay confirmed that MK2206 inhibited GCLC promoter activity in HCC193 and H1993 cells (Fig. 5B), indicating that the transcriptional activity of NRF2 was inhibited by MK2206. Similarly, AKT-DN inhibited the transcriptional activity of NRF2 in HCC193 and H1993 cells in a luciferase reporter assay (Fig. 5C and D), and reduced NRF2 in the nuclear fractions of H1993 cells (Fig. 5E). Downregulation of GCLC mRNA was also observed in both HCC193 and H1993 cells with a time point–dependent manner (Fig. 5F). Because GCLC is a rate-limiting molecule for GSH synthesis and GSH is the major ROS scavenger, we further determined GSH production in cells treated with MK2206. The GSH level was dramatically reduced in cells treated with MK2206 or combination in HCC193 and H1993 cells (Fig. 5G). These results indicate that MK2206 inhibited NRF2 transcriptional activity and its downstream molecules, such as GCLC, which subsequently reduced the GSH level and resulted in ROS induction.

**Synthetic lethality induced by MK2206 and auranoﬁn depends on the genetic status of KEAP1**

The above results indicate that the synthetic lethality induced by MK2206 and auranoﬁn is mediated by ROS through concurrent inhibition of NRF2 and TXNRD1, two major cellular redox regulators. Because KEAP1 mutations cause constitutive activation of NRF2 (38, 39), which we expect will not be inhibited by MK2206 and thereby cause resistance to MK2206 and auranoﬁn combination. To test this hypothesis, we tested 5 additional KEAP1 wild-type cell lines (H1299, H23, H358, H292, and H1703), 5 KEAP1-inactive mutant cell lines (H460, A549, H2126, H1648, and H838), and 2 heterozygous mutant cell lines (H1993 and H1395) for their sensitivity to treatment with MK2206 and auranoﬁn combination.
MK2206, aurano, or both (18, 19). All KEAP1 wild-type cell lines and heterozygous mutant cell lines were sensitive to MK2206–aurano combination based on the IC50 of MK2206, which are below or close to 1 μmol/L, a clinical achievable dose (Fig. 6A and Supplementary Table S1). In contrast, all KEAP1-mutant cells were not responsive to the combination treatment (IC50s of MK2206 are more than the 3 μmol/L; Fig. 6B and Table 1). Statistical analysis revealed that the cell lines’ sensitivity to the combination of MK2206 and aurano was significantly correlated with the KEAP1 genetic status (P = 0.0013); no correlation was found between cell lines’ sensitivity and other mutations, including KRAS and LKB1 mutations (Table 1). Combination of aurano and MK2206 induced PARP cleavage in KEAP1 wild-type H1299 but not in KEAP1-mutant H460 cell lines (Fig. 6C). Our results indicate that synthetic lethality induced by MK2206 and aurano depends on the genetic status of KEAP1. Using an EGFP–NRF2 fusion protein, we confirmed that MK2206 induced NRF2 nuclear exclusion in KEAP1 wild-type H1299 cells but not in KEAP1-mutant H460 cells (Fig. 6D). Moreover, MK2206 could not inhibit NRF2 transcriptional activity by MK2206 in KEAP1-mutant H460 and A549 cells in a Luciferase reporter assay (Fig. 6E). These results indicate that constitutive activation of NRF2 due to inactive KEAP1 mutations cannot be overcome by MK2206, thus causing resistance to aurano and MK2206 combination. To further confirm this, KEAP1 was stably knocked down in KEAP1 wild-type H1299 cells (Fig. 6F, left). KEAP1 knockdown rendered cells’ resistance to the...

combination treatment (Fig. 6F, middle and right). Whereas overexpression of wild-type KEAP1 (32), DsRed-KEAP1 (D-

KEAP1) fusion gene in KEAP1-mutant H460 cells sensitized the cells to this combination (Fig. 6G). The apoptosis marker,

PARP cleavage was also induced by the combination treatment in H460 cells with overexpression of a wild-type KEAP
(Supplementary Fig. S1). These results confirmed that synthetic lethality induced by MK2206 and auranofin depends on a functional KEAP1 gene. Collectively, our results indicate that combination of auranofin and MK2206 concurrently inhibits TXNRD1 and NRF2, two major cellular antioxidant systems in KEAP1 wild-type NSCLC cells, and induces ROS production and cell apoptosis. A model of synthetic lethality induced by combination of MK2006 and aurano
tic lethal lethality induced by MK2206 and AKT inhibitor was shown in Fig. 6H.

Discussion

In this study, we conducted a genome-wide siRNA library screening with NSCLC cell line HCC193 to identify the genes that can be targeted to sensitize the cells to AKT inhibitor MK2206. This screening revealed 156 MK2206 synthetic lethality hits (genes) with a FDR of 0.1, and a minimum 50% inhibition with combination of siRNA and 1 μmol/L MK2206. Those hits include previously reported autophagy-related genes, such as MAP1LC3C, cathepsin E, and cathepsin H, and components in the NF-κB pathway, such as CASP8 and CFLAR. Inhibition of autophagy could sensitize the cells to PI3K/AKT inhibitor treatment, which has been reported previously (40, 41). Other hits include ATPases and ATP synthase members, such as ATP5J and ATP6V1B1, both of which are H+ transporters. The synthetic lethality interaction between AKT and ATPases may occur through the autophagy pathway as previous studies reported that the vacuolar membrane H+-ATPase plays an important role in autophagy (42, 43). The synthetic lethality hits are related to different pathways, and many of those hits or pathways have cross-talk (44, 45). This screening result confirmed some previous finding such as synthetic lethality induced by autophagy and AKT inhibition but also revealed some novel targets, such as TXNRD1, the molecules in redox balance, suggesting potential synthetic lethal interactions between the redox regulation system and AKT pathways.

Previous studies indicate that other pathways, such as KEAP1/NRF2, may compensate some functions of the TXNRD1/TXN in cancer cells especially in vivo. In addition, oncogenic pathways such as KRAS and NF-κB also regulate the cellular redox balance through interaction with TXNRD1 or KEAP1/NRF2 (46–49), suggesting complicated interaction between oncogenic signaling pathways and cellular redox balance system. Here, we showed that concurrent inhibition of TXNRD1 and AKT pathways with auranofin and MK2206, respectively, induced robust ROS production and NSCLC cell apoptosis in vitro and tumor growth inhibition in vivo, which was not achieved by each drug alone. More importantly, NDGA, a ROS blocker, rescued the cell growth inhibition, JNK activation, and PARP cleavage induced by the auranofin and MK2206 combination. Our results indicate that interruption of the cellular redox balance plays an important role in the synthetic lethality induced by simultaneous inhibition of TXNRD1 and AKT. We found that MK2206 inhibited the NRF2 activity and reduced the GSH level through downregulating GCLC expression, which is consistent with a recent study that inhibition of mTOR reduced GSH level and induced ROS in KRAS-mutant lung cancer (50). Because mTOR pathway is regulated by AKT, it is also possible that MK2206-induced ROS production may be mediated by both NRF2 and mTOR inhibition. Nevertheless, our results indicate that targeting the interactions between the PI3K/AKT oncogenic pathway and cellular antioxidant system, TXNRD1 and KEAP1/NRF2, will disrupt cancer redox homeostasis and might be a promising cancer therapeutic approach.

Loss-of-function mutations of KEAP1 occur in many cancer types and KEAP1 mutations cause constitutive activation of NRF2 (18–20). Because the combination of auranofin and MK2206 induced synthetic lethality by simultaneous inhibition of the TXNRD1 and NRF2 pathways, we hypothesized that KEAP1 mutations might render cancer cells resistant to the combination of MK2006 and auranofin. Our results showed

Published OnlineFirst July 3, 2013; DOI: 10.1158/0008-5472.CAN-13-0712
that lung cancer cells with wild-type KEAP1 were particularly sensitive to MK2206 and auranofin, whereas cells with mutant KEAP1 were not as sensitive. This finding was further supported by evidence that MK2206 induced NRF2 nuclear exclusion and transcriptional activity in KEAP1 wild-type cells but not in KEAP1-mutant cells. In addition, KEAP1 knockdown in KEAP1 wild-type cells or reexpression of functional KEAP1 in KEAP1-mutant cells reversed the sensitivity to auranofin and MK2206 treatment. These findings indicate that the synthetically lethal activity induced by MK2206 and auranofin depends on a functional KEAP1 gene. Further study of the genetic mutations in this pathway and their association with drug sensitivity may be useful for the identification of predictive biomarkers.

In summary, we identified a set of synthetic loci that could be targeted to improve the antitumor activity of AKT inhibitor MK2206. We discovered that the synthetic lethal interaction between the AKT pathway and TXNRD1 occurs through the KEAP1/NRF2 antioxidant system, and targeting such interaction with a combination of AKT inhibitor and auranofin is a promising approach for lung cancer therapy, with KEAP1 mutation status as a genetic biomarker of drug sensitivity.
